## Message from the Director General

The National Institute of Education takes opportune steps from time to time for the development of quality in education. Preparation of supplementary resource books for respective subjects is one such initiative.

Supplementary resource books have been composed by a team of curriculum developers of the National Institute of Education, subject experts from the national universities and experienced teachers from the school system. Because these resource books have been written so that they are in line with the G. C. E. (A/L) new syllabus implemented in 2017, students can broaden their understanding of the subject matter by referring these books while teachers can refer them in order to plan more effective learning teaching activities.

I wish to express my sincere gratitude to the staff members of the National Institute of Education and external subject experts who made their academic contribution to make this material available to you.

Dr. (Mrs.) T. A. R. J. Gunasekara<br>Director General<br>National Institute of Education<br>Maharagama.

## Message from the Director

Since 2017, a rationalized curriculum, which is an updated version of the previous curriculum is in effect for the G.C.E (A/L) in the general education system of Sri Lanka. In this new curriculum cycle, revisions were made in the subject content, mode of delivery and curricular materials of the G.C.E. (A/L) Physics, Chemistry and Biology. Several alterations in the learning teaching sequence were also made. A new Teachers’ Guide was introduced in place of the previous Teacher's Instruction Manual. In concurrence to that, certain changes in the learning teaching methodology, evaluation and assessment are expected. The newly introduced Teachers' Guide provides learning outcomes, a guideline for teachers to mould the learning events, assessment and evaluation.

When implementing the previous curricula, the use of internationally recognized standard textbooks published in English was imperative for the Advanced Level science subjects. Due to the contradictions of facts related to the subject matter between different textbooks and inclusion of the content beyond the limits of the local curriculum, the usage of those books was not convenient for both teachers and students. This book comes to you as an attempt to overcome that issue.

As this book is available in Sinhala, Tamil, and English, the book offers students an opportunity to refer the relevant subject content in their mother tongue as well as in English within the limits of the local curriculum. It also provides both students and teachers a source of reliable information expected by the curriculum instead of various information gathered from the other sources.

This book authored by subject experts from the universities and experienced subject teachers is presented to you followed by the approval of the Academic Affairs Board and the Council of the National Institute of Education. Thus, it can be recommended as a material of high standard.

Dr. A. D. A. De Silva

## Introduction

Everything in the universe has a chemical identity. We know that the smallest particle of matter is an atom. "Study of matter and the changes that it undergoes" can simply be understood as the basic definition of chemistry. Usually matter is anything that occupies space and has mass and can be seen and touched (such as soil, water) as well as things we cannot see such as air. Based on the composition and properties, several categories such as substances, mixtures, elements as well as atoms and molecules can be identified. All substances, at least in principle, can exist in three states: solid, liquid and gas. In a solid, particles are held tightly and close together in an ordered structure with a definite shape having a small degree of motion. Particles in a liquid are close together but are not held so tightly in position and can move faster compared to that of solid. Gases differ largely from liquids and solids in the distances between the particles. In a gas, the particles are separated by distances, large compared with the size of the particles allowing them to behave freely. Therefore, the attractive forces between gas particles are very small or negligible and that allows us to consider gas particles individually and some hypotheses are easily predictable depending on the temperature and pressure changes.

### 1.1 Organization of particles in three principal states and their typical characteristics

Anything that occupies space and has a mass can be called "matter". This could be things we can see and touch like trees or things we cannot see like the air we breathe. All matter can be classified broadly into three states solid, liquid and gas. Matter can be interconverted among these three states without changing the composition. For an example water in liquid state can be converted to gaseous state (steam) when heated and can be converted to a solid (ice) if cooled.

Solid (eg. nail)
Fixed shape
and volume

## Solid

Strong interparticle (atoms, molecules or ions) forces. Particles vibrate but cannot move around.

Liquid (eg. water) No Fixed shape but has fixed volume

Liquid
Moderate interparticle (atoms, molecules or ions) forces. Particles can move around up to some extent.

Gas (eg. He balloons) No fixed shape and no fixed volume

Gas
Weak interparticle (atoms, molecules or ions) forces. Particles can move around.

Figure 1.1 Three states of matter

Three states of matter differ based on arrangement and movement of particles. The interparticle distance is highest in gaseous state and lowest in solids. In liquid state, particles are relatively closer compared to gaseous state, yet not too close compared to the solid state. Therefore, a regular pattern of particles can be seen only in solid state, while both gaseous and liquid state particles show random arrangement. As a result, particles in gaseous state can move fast and freely compared to liquid state particles. However, movement of particles in solids is limited to vibrations. The arrangement and motions of particles in matter result in differences in macroscopic properties such as volume, shape, compressibility and density as indicated in the Table 1.1 below.

Table 1.1 Qualitative comparison of properties of solids, liquids and gases

| Property | Solids | Liquids | Gases |
| :--- | :--- | :--- | :--- |
| Shape | Definite | Take up shape of <br> the container but do <br> not spread <br> throughout the <br> entire volume of the <br> container | Take up the shape of <br> the container and <br> occupy the entire <br> volume of the <br> container |
| Volume | Definite | Definite | Occupy the volume of <br> the container |
| Density <br> $(\rho) / \mathrm{g} \mathrm{cm}^{-3}$ <br> at 293 K | Have high values <br> eg.: Iron <br> $(7.874 \mathrm{~g} \mathrm{~cm}$ |  |  |
| Compressibility | Have moderately <br> high values <br> eg.: Water <br> $(0.997 \mathrm{~g} \mathrm{~cm}$ | Have low values <br> eg.: Hydrogen <br> $(0.071 \mathrm{~g} \mathrm{~cm}$ |  |
| compress $)$ |  |  |  |

Note: Here we say that a liquid takes the shape of the container and we have to think why we get these shapes. Usually, particles of any object is being pulled by a variety of forces such as intermolecular forces, and that's why it has shape. Some given amount (volume) of water in a beaker is being shaped by surface tension resulting from intermolecular forces within the liquid creating a meniscus curve at the edge of the surface, by the force of the walls of the beaker pushing up on it, and by the gravity which is greater than the surface tension, pulling it down. So, it takes the shape of the beaker, with a flat surface on the top. This happens due to the satisfaction of all those different forces. However, in the case that the surface tension is stronger than gravity, the water's surface might not lie flat by taking the shape of the container. Assume that there is no gravity, and so surface tension is very much high. As each part of the surface wants to stay as close as possible to the rest of the surface it tries to minimize the forces within. So, the shape that best allows this is a sphere, because it is the shape that has the minimal surface area for a given volume.

Matter in one particular state can be converted to another state by heating or cooling. Increase of temperature makes particles move faster and inter-particle distance becomes greater leading to change in state. Accordingly, increase in temperature converts solid state materials to liquid and liquid state materials to gaseous state. The opposite happens with decreasing temperature. Figure 1.2 illustrates how matter can be interconverted among states.

Figure 1.2 Interconversion of states of matter

## Example 1.1

In which state of matter are the particles mostly touching but arranged in a random way?

## Answer

Liquid State

When we describe the properties of the three states of matter with the help of Table 1.1, motion and arrangement of particles are basically considered. Especially, thermal energy is the energy of a body arising from motion of its atoms or molecules and it is directly proportional to the temperature of the substance. Therefore, it measures the average kinetic energy of the particles of the matter and is thus responsible for movement of particles or the thermal motion.

As we already know, interparticle forces tend to keep the particles together but thermal energy of the particles tends to keep them apart. Therefore the existence of three states of matter can be regarded as a result of balance between interparticle forces and the thermal energy of the particles.

When inter molecular interactions are very weak, molecules do not tend to make liquid or solid unless thermal energy is reduced by lowering the temperature. Gases do not liquefy on compression only, although molecules come very close to each other and intermolecular forces operate to the maximum. However, when thermal energy of molecules is reduced by lowering the temperature, the gases can very easily be liquefied. These behaviours can be explained by Figure 1.3 where we can understand the reversible nature of intermolecular forces and the thermal energy acting on the three states of matter.

Intermolecular forces increase
Gas $\longrightarrow$ Liquid $\longrightarrow$ Solid
Gas $\longrightarrow$ Liquid $\longrightarrow$ Solid

Thermal energy decrease

Figure 1.3 Behaviour of three states of matter against intermolecular forces and thermal energy

We have already learnt the cause for the existence of the three states of matter. Now we will learn more about the gaseous state and the laws which govern the behaviour of matter in this state.

### 1.2 Gaseous state

Let us now focus our attention on the behaviour of substances which exist in the gaseous state under normal conditions of temperature and pressure.

The gaseous state is characterized by the following physical properties as described in Table 1.1.

- Gases are highly compressible.
- Gases exert pressure equally in all directions.
- Gases have much lower density than the solids and liquids.
- The volume and the shape of gases are not fixed. These assume volume and shape of the container.
- Gases mix evenly and completely in all proportions without any mechanical aid.

Simplicity of gas is due to the fact that the forces between their molecules are negligible. Their behaviour is governed by same general laws (will be discussed later), which were discovered as a result of experimental studies. These laws are usually relationships between measurable properties of gases. Some of these properties like pressure, volume, temperature and amount (moles or mass) are very important because relationships between these variables describe state of the gas (will be defined in unit 5). Interdependence of these variables leads to the formulation of gas laws.

### 1.2.1 Gas laws

The gas laws that we are going to discuss are the results of experiments carried out by several scientists on the physical properties of gases. In these experiments, relations among the variables of pressure, temperature, volume and amount of gases are considered and the results provide valuable information on the gaseous state of matter in turn helping the mankind in many ways.

## Ideal gas and ideal gas equation

When it is assumed that intermolecular forces do not exist among the molecules of a gas, such a gas is called an ideal gas. That is molecules in an ideal gas do not exhibit attraction or repulsion among them. Furthermore, the volume of ideal gas particles is considered negligible when compared to the volume of the container.

The absolute temperature ( $T$ ), pressure $(P)$, volume ( $V$ ) and the amount ( $n$, moles) of a gas are the factors that affect the behaviour of a gas. $P, T, V$ and $n$ are related by the expression;

$$
P V=n R T
$$

This is known as the ideal gas equation or ideal gas law where the gas constant $R$ is same for every gases. Any gas which obeys the above relationship under any given temperature and pressure is referred to as an ideal gas.

The value of the constant $R$ for one mole of an ideal gas can be calculated under the conditions of $0^{\circ} \mathrm{C}$ and 1 atm as given below: (At $0^{\circ} \mathrm{C}$ and 1 atm , the volume of one mole of ideal gas is $22.414 \mathrm{dm}^{3}$ )

$$
R=\frac{P V}{n T}=\frac{101325 \mathrm{~Pa} \times 22.414 \times 10^{-3} \mathrm{~m}^{3}}{1 \mathrm{~mol} \times 273.15 \mathrm{~K}}=8.314 \mathrm{~J} \mathrm{~K}^{-1} \mathrm{~mol}^{-1}
$$

We can see that the ideal gas equation is a relationship among four variables and it describes the state of any gas. Therefore, it is also called equation of state.

## Calculations based on ideal gas equation

The ideal gas law allows us to determine any one of the quantities volume, pressure, temperature, or moles of the gas when the other three are given. If the amount of moles of the gas is known, we can also calculate its mass using its molar mass. Further it can also be used to determine the density of a gas. It is important to keep in mind that all the other quantities must be in units that match the value used for the ideal gas constant. Usually pressure can be expressed in several units such as atm, Pa, bar, torr, etc. Therefore, in solving these problems it may helpful to use pressure conversions as given in the Table 1.2.

Table 1.2 Pressure units

| Pressure unit | Pa | bar | atm | torr $/ \mathbf{m m H g}$ |
| :--- | :--- | :--- | :--- | :--- |
| 1 Pa | $1 \mathrm{~N} \mathrm{~m}^{-2}$ | $10^{-5}$ | $9.87 \times 10^{-6}$ | $7.5 \times 10^{-3}$ |
| 1 bar | 100,000 | 1 bar | 0.987 | 750.06 |
| 1 atm | 101,325 | 1.01325 | 1 atm | 760 |
| 1 torr $/ \mathrm{mmHg}$ | 133.32 | $1.3332 \times 10^{-3}$ | $1.3158 \times 10^{-3}$ | 1 torr/ 1 mmHg |

## Example 1.2

The volume of a gas cylinder is $0.950 \mathrm{dm}^{3}$. When filled, the cylinder contains liquid propane $\left(\mathrm{C}_{3} \mathrm{H}_{8}\right)$ stored under pressure. When the cylinder is empty, it contains some residual propane gas molecules at atmospheric pressure and temperature.
(i) Calculate the number of moles of propane gas remaining in a cylinder when it is empty if the surrounding atmospheric conditions are $25.0^{\circ} \mathrm{C}$ and 750 torr ( 1 torr $=133.32 \mathrm{~Pa}$ ) (when the internal pressure equals to the external pressure).
(ii) Calculate the mass of propane remaining in the cylinder.
(iii) Calculate the density of remaining propane gas in the cylinder.

## Answer

(i) First summarize the given information;

$$
\text { Temperature, } \mathrm{T}=(25+273) \mathrm{K}=298 \mathrm{~K}
$$

Pressure, $\mathrm{P}=750$ torr $\times 133.32 \mathrm{~Pa} / 1$ torr $=99990 \mathrm{~Pa}$
Volume, $\mathrm{V}=0.950 \mathrm{dm}^{3}=0.950 \times 10^{-3} \mathrm{~m}^{3}$
Unknown is n
Using $P V=n R T$;

$$
n=\frac{P V}{R T}=\frac{99990 \mathrm{~Pa} \times 0.950 \times 10^{-3} \mathrm{~m}^{3}}{8.314 \mathrm{~J} \mathrm{~K}^{-1} \mathrm{~mol}^{-1} \times 298 \mathrm{~K}}=0.038 \mathrm{~mol}
$$

(ii) Molar mass of propane $\left(\mathrm{C}_{3} \mathrm{H}_{8}\right)=44 \mathrm{~g} \mathrm{~mol}^{-1}$

$$
\text { Mass of propane }=0.038 \mathrm{~mol} \times 44 \mathrm{~g} / 1 \mathrm{~mol}=1.672 \mathrm{~g}
$$

(iii) Density of propane $=$ mass $/$ volume $=1.672 \mathrm{~g} / 0.950 \mathrm{dm}^{3}=1.76 \mathrm{~g} \mathrm{dm}^{-3}$

When we consider the above example, there are insights into the ideal gas equation that it can be expressed in different forms to estimate mass and density of a given gas with simple modifications as shown below.
$P V=n R T$ and we can write,
$P=\frac{n}{V} R T$

$$
\therefore P=C R T
$$

where $C$ is the concentration
We can also write $P V=n R T$ as

$$
P V=\frac{m}{M} R T
$$

where, $m$ is the mass and $M$ is the molar mass of the gas.
Also we can write the above as;

$$
P=\frac{1}{M}\left(\frac{m}{v}\right) R T
$$

$$
\therefore P=\frac{d R T}{M}
$$

where, $d$ is the density and $d=\frac{m}{v}$
Ideal gas law serves as the basis when deriving several other gas laws under specific conditions.

### 1.2.2 Boyle law (pressure - volume relationship)

That is the "pressure of a fixed amount (mass) of gas at constant temperature inversely varies with (or proportional to) the volume of the gas". This is known as the Boyle Law (1627-1691) which was named after Robert Boyle, an Irish scientist in the seventeenth century who studied change in volume of a gas when pressure of a gas is varied under constant temperature conditions. Mathematical form of it, is given below.

$$
P \propto \frac{1}{V} \text { or } P=\frac{k}{V} ; \mathrm{k} \text { is a constant }
$$

The ideal gas law can be used to derive Boyle law as follows.

$$
P V=n R T
$$

If the amount of the gas and temperature of the system are kept constant, then the product $n T$ is a constant. Since $R$ is also a constant, then the product, $n R T=k$ (a constant)

$$
P V=k
$$

It means that "at constant temperature, the product of pressure and volume of a fixed amount of gas is constant". This is another way of expressing Boyle law.

If a fixed amount of gas at constant temperature $T$ occupying volume $V_{1}$ at pressure $P_{1}$ undergoes change, so that volume becomes $V_{2}$ and pressure becomes $P_{2}$, then according to Boyle law:

$$
P_{1} V_{1}=P_{2} V_{2}
$$

Figure 1.4 shows two conventional ways of graphical representation of Boyle law. Figure 1.4 (a) is the graph of $P V=k$ at different temperatures for the comparison. The value of $k$ for each curve is different because for a given mass of gas, it varies only with temperature. Note that at higher temperatures, curves shift upwards due to the expansion of volume. It should also be noted that volume of the gas doubles if pressure is halved at a constant temperature.

Figure 1.4 Changes in pressure at different constant temperatures with respect to (a) volume ( $V$ ) changes and (b) with $1 / V$

Figure 1.4 (b) represents the graph of $P$ vs $1 / V$. It is a straight line passing through the origin. These plots obtained by the experiments carried out by Boyle, show in a quantitative manner that gases are highly compressible. That is because when a given mass of a gas is compressed, the same number of molecules will occupy a smaller space. This means that gases become denser at high pressures.

Note: We know that density (d) of a given mass ( $m$ ) occupying volume $(V)$ is given by; $d=m / V$. Therefore at constant temperature we can write, $d=\left(\frac{m}{k / P}\right)=\left(\frac{m}{k}\right) P=k^{\prime} P$

## Example 1.3

Calculate the change in pressure of a gas when the volume is doubled at constant temperature for a known amount of a gas.

## Answer

$V_{l}=V, V_{2}=2 V, P_{1}=P, P_{2}=$ ?
Applying Boyle law: $P_{1} V_{1}=P_{2} V_{2}$
$P \times V=P_{2} \times 2 V$
$P_{2}=P / 2$
$\therefore$ New pressure is half the initial pressure.

## Example 1.4

A balloon is to be filled with a known amount of hydrogen gas at room temperature. At atmospheric pressure ( 100 kPa ), the gas occupies $2.50 \mathrm{dm}^{3}$ volume. What would be the volume of the balloon when the pressure inside is 20 kPa at the same temperature.

## Answer

$$
P_{1}=100 \mathrm{kPa}, P_{2}=20 \mathrm{kPa}, V_{l}=2.5 \mathrm{dm}^{3}, V_{2}=?
$$

Applying Boyle law: $P_{1} V_{l}=P_{2} V_{2}$

```
100 kPa }\times2.5\mp@subsup{\textrm{dm}}{}{3}=20\textrm{kPa}\times\mp@subsup{V}{2}{
```

$$
\therefore V_{2}=12.5 \mathrm{dm}^{3}
$$

The balloon is filled up to the volume of $12.5 \mathrm{dm}^{3}$.

### 1.2.3 Charles law (temperature - volume relationship)

Investigations by the scientists Jacques Charles and Joseph Gay-Lussac have showed that for a fixed amount (mass) of a gas at constant pressure volume of a gas increases on heating and decreases on cooling. It was also found that for each degree change (rise or fall) in temperature, volume of a gas changes (increases or decreases) by a factor of $1 / 273.15$ of the original volume of the gas at $0^{\circ} \mathrm{C}$.

Assume that volumes of the gas at $0{ }^{\circ} \mathrm{C}$ and at $t^{\circ} \mathrm{C}$ are $V_{0}$ and $V_{\mathrm{t}}$ respectively, then we can write,

$$
V_{t}=V_{0}+\left(\frac{t}{273.15}\right) V_{0}=V_{0}\left(1+\frac{t}{273.15}\right)=V_{0}\left(\frac{273.15+t}{273.15}\right)
$$

At this stage, a new scale of temperature is defined such that $t^{\circ} \mathrm{C}$ on new scale is given by

$$
T_{t}=273.15+t
$$

and $0^{\circ} \mathrm{C}$ will be given by

$$
T_{0}=273.15
$$

This new temperature scale is called the Kelvin temperature scale (K) or absolute temperature scale. $-273.15^{\circ} \mathrm{C}(0 \mathrm{~K})$ is also defined as the thermodynamic zero, which is the lowest theoretically reachable temperature.
By applying this temperature scale, we can rewrite the relation $V_{t}=V_{0}\left(\frac{273.15+t}{273.15}\right)$ as,

Hence,

$$
V_{t}=V_{0}\left(\frac{T_{t}}{T_{0}}\right)
$$

$$
\frac{V_{t}}{V_{0}}=\frac{T_{t}}{T_{0}}
$$

For a general case when the change occurs from $\left(V_{1}, T_{1}\right)$ to $\left(V_{2}, T_{2}\right)$ at constant pressure

$$
\frac{V_{1}}{V_{2}}=\frac{T_{1}}{T_{2}}
$$

This can be rearranged as

$$
\begin{gathered}
\frac{V_{1}}{T_{1}}=\frac{V_{2}}{T_{2}} \\
\frac{V}{T}=\text { constant or } V=k T
\end{gathered}
$$

Therefore, "the volume of a fixed amount of gas under constant pressure is directly proportional to the absolute temperature of the gas." This is called Charles law.

Further, the ideal gas law can be used to study the effect of temperature on the volume of a gas if the pressure of the system is kept constant for a fixed amount of a gas. The ideal gas law can be rearranged as follows;

$$
\begin{gathered}
P V=n R T \\
V=n R T / P
\end{gathered}
$$

When the pressure of a fixed mass of gas is constant, $\frac{n R}{P}$ is constant.

$$
\therefore \boldsymbol{V} \propto \boldsymbol{T} \text { or } \boldsymbol{V}=\boldsymbol{k} \boldsymbol{T}
$$

According to Charles law for all gases, at any given pressure, graph of volume versus, temperature (in Celsius) is a straight line and on extending to zero volume, each line intercepts the temperature axis at $-273.15{ }^{\circ} \mathrm{C}$. Slopes of lines obtained at different pressure are different but at zero volume all the lines meet the temperature axis at -273.15 ${ }^{\circ} \mathrm{C}$ or 0 K as shown in Figure 1.5.

Figure 1.5 Changes in volume of a gas with respect to temperature change at different constant pressures

## Example 1.5

Calculate the change in temperature of a gas when the volume is tripled at constant pressure for a known amount of gas moles.

> Answer
> $V_{l}=V, V_{2}=3 V, T_{1}=T, T_{2}=?$
> $V_{l} / V_{2}=T_{1} / T_{2}$
> $V / 3 V=T / T_{2}$
> $T_{2}=3 T$

This can further be estimated directly, as the volume is directly proportional to Kelvin temperature T , the new temperature would be thrice the initial value, i.e 3 T .

Let's consider the equation $V_{t}=V_{0}\left(\frac{273.15+t}{273.15}\right)$ and substitute $\mathrm{t}=-273.15$, where we get the volume of the gas equal to zero meaning that the gas will not exist. Therefore, we can understand that all the gases get liquefied before this temperature is reached. The lowest hypothetical or imaginary temperature at which gases are supposed to occupy zero volume is called absolute zero.

## Example 1.6

A balloon is filled with a known amount of hydrogen gas resulting a volume of 2.0 $\mathrm{dm}^{3}$ at $23^{\circ} \mathrm{C}$. Calculate the change in volume of a gas when the temperature is increased to $27^{\circ} \mathrm{C}$ at the same pressure.

## Answer

$$
T_{1}=23+273=296 \mathrm{~K}, T_{2}=27+273=300 \mathrm{~K}, V_{l}=2.0 \mathrm{dm}^{3}, \mathrm{~V}_{2}=?
$$

Applying Charles law as the pressure and amount of gas constant,

$$
\frac{V_{1}}{T_{1}}=\frac{V_{2}}{T_{2}}
$$

$$
\begin{aligned}
& \frac{2.0 \mathrm{dm}^{3}}{296 \mathrm{~K}}=\frac{V_{2}}{300 \mathrm{~K}} \\
& V_{2}=2.03 \mathrm{dm}^{3}
\end{aligned}
$$

Therefore, the change in volume is $0.03 \mathrm{dm}^{3}$

### 1.2.4 Avogadro law (amount - volume relationship)

Upon the developments of Boyle and Charles laws, in 1811 Italian scientist Amedeo Avogadro tried to combine conclusions of those with the amount and volume of a gas and postulated a new hypothesis which is now known as Avogadro law. It states that equal volumes of all gases under the same conditions of temperature and pressure contain equal number of moles (Avogadro Law).

> i.e. $\quad \mathrm{V} \propto \mathrm{n}$ or we can write $V=k n$

The number of molecules in one mole of a gas has been determined to be $6.022 \times 10^{23}$ and also known as Avogadro constant (denoted as $\mathrm{N}_{\mathrm{A}}$ or L ).

Avogadro law can be easily understood with the help of the ideal gas law as follows.

$$
\begin{gathered}
P V=n R T \\
V=\frac{R T}{P} \times n \\
V=\frac{R T}{P} \times \frac{N}{N_{A}}=\frac{R T}{P N_{A}} \times N
\end{gathered}
$$

Here, $N$ and $N_{A}$ are the number of molecules of the gas and the Avogadro constant respectively. By applying the above relationships to equal volumes of gases P and Q at the same temperature and pressure,

$$
\begin{aligned}
& V_{P}=\frac{R T}{P N_{A}} \times N_{P} \\
& V_{Q}=\frac{R T}{P N_{A}} \times N_{Q}
\end{aligned}
$$

At constant $P$ and $T$, we can write (as $R$ and $N_{A}$ are constants)

$$
V_{P} / V_{Q}=N_{P} / N_{Q}
$$

Simply it says that for a gas at constant temperature and pressure equal volumes of gases have equal number of molecules. i.e. $V \alpha N$

It is useful to understand that the gas laws discussed above can also be used to obtain the ideal gas equation for a given volume $V$ of a gas.

$$
\begin{aligned}
& \text { Boyel Law : } \quad V \propto \frac{1}{P}-----(1) \\
& \text { Charles Law : } V \propto T \quad----(2)
\end{aligned}
$$

Avogardro Law : $V \propto n----$ (3)
The only equation that fulfills (1), (2) and (3) is,

$$
\begin{aligned}
& V \propto \frac{n T}{P} \\
& \frac{P V}{n T}=k \\
& \text { When } k=R \\
& P V=n R T
\end{aligned}
$$

### 1.2.5 Molar volume ( $V_{m}$ )

Since volume of a gas is directly proportional to the number of moles we can write,

$$
V_{m}=\frac{V}{n}
$$

As temperature and pressure are the same, one mole of any gas should occupy the same volume $V_{m}$ and that can be calculated as,

$$
V_{m}=\frac{R T}{P}
$$

Therefore, at temperature and standard pressure molar volume $\left(V_{m}\right)$ of any gas should have the same volume. There are two sets of conditions applied for the standard value.

- In the first set of condition; the temperature is taken as $0^{\circ} \mathrm{C}(273.15 \mathrm{~K})$ and the standard pressure as 1 atm ( 101325 Pa ). At this standard condition molar volume of an ideal gas or a combination of ideal gases is $22.414 \mathbf{~ d m}^{3} \mathbf{~ m o l}^{-1}$. Molar volume under these conditions is denoted as $\boldsymbol{V}_{\boldsymbol{m}}^{\Theta}$.
- In the second set of condition; the ambient temperature is taken as $25{ }^{\circ} \mathrm{C}$ (298.15 K) and the standard pressure as 1 atm (101325 Pa). In that case, the molar volume of a gas has the value $24.790 \mathrm{dm}^{3} \mathrm{~mol}^{-1}$.

Note: From Avogadro law we can see that the molar mass (M) of a gas is directly proportional to its density (d).

$$
V=k n=k(m / M),
$$

therefore $M=k(m / V)=k d$

## Example 1.7

Show that the molar volumes of 1 mole of He and 1 mole of Ne gas at 298 K temperature and 1 atm pressure are the same.

$$
\begin{aligned}
& \text { Answer } \\
& P_{H e}=1 \mathrm{~atm}=101325 \mathrm{~Pa}, T_{H e}=298 \mathrm{~K}, n_{H e}=1.00 \mathrm{~mol}, V_{H e}=? \\
& P_{H e} V_{H e}=n_{H e} R T_{H e} \\
& V_{H e}=n_{H e} R T_{H e} / P_{H e} \\
& V_{H e}=\left(1 \mathrm{~mol} \times 8.314 \mathrm{~J} \mathrm{~K}^{-1} \mathrm{~mol}^{-1} \times 298 \mathrm{~K}\right) / 101325 \mathrm{~Pa}=24.4 \mathrm{dm}^{3} \\
& P_{N e}=1 \mathrm{~atm}=101325 \mathrm{~Pa}, T_{N e}=298 \mathrm{~K}, n_{N e}=1.00 \mathrm{~mol}, V_{N e}=? \\
& P_{N e} V_{N e}=n_{N e} R T_{N e} \\
& V_{N e}=n_{N e} R T_{N e} / P_{N e} \\
& V_{N e}=\left(1 \mathrm{~mol} \times 8.314 \mathrm{~J} \mathrm{~K}^{-1} \mathrm{~mol}^{-1} \times 298 \mathrm{~K}\right) / 101325 \mathrm{~Pa} \\
& V_{N e}=24.4 \mathrm{dm}^{3}
\end{aligned}
$$

i.e. at the same temperature and pressure, if number of moles are the same, then different gases will occupy the same volume.

### 1.2.6 Combined gas law

As all gases behave the same way with respect to pressure, volume, and temperature, if the amount is measured per mole, then the ideal gas expression itself can be written as a ratio useful in the events like when temperature, volume, and pressure of a fixed amount of gas vary from $\left(T_{1}, V_{1}, P_{1}\right)$ to $\left(T_{2}, V_{2}, P_{2}\right)$. For such an instance we can write, for the initial condition; $n R=\frac{P_{1} V_{1}}{T_{1}}$
for the final condition; $n R=\frac{P_{2} V_{2}}{T_{2}}$

$$
\frac{P_{1} V_{1}}{T_{1}}=\frac{P_{2} V_{2}}{T_{2}}
$$

This is called the combined gas law.

## Example 1.8

At $25^{\circ} \mathrm{C}$ and 760 mm Hg pressure, a given amount of a gas occupies a volume of 600 $\mathrm{cm}^{3}$. What will be its pressure at $10^{\circ} \mathrm{C}$ when volume of the gas is $650 \mathrm{~cm}^{3}$.

## Answer

$$
\begin{aligned}
& \left(T_{1}, V_{1}, P_{1}\right) \text { to }\left(T_{2}, V_{2}, P_{2}\right) \text { we can write } \\
& P_{1}=760 \mathrm{~mm} \mathrm{Hg}=1 \mathrm{~atm}=101325 \mathrm{~Pa}, V_{1}=600 \mathrm{~cm}^{3}=0.600 \mathrm{dm}^{3}, T_{1}=25+273= \\
& 298 \mathrm{~K}
\end{aligned}
$$

$$
V_{2}=650 \mathrm{~cm}^{3}=0.650 \mathrm{dm}^{3}, T_{2}=10+273=283 \mathrm{~K}, P_{2}=?
$$

$$
\text { According to Combined gas law; } \frac{P_{1} V_{1}}{T_{1}}=\frac{P_{2} V_{2}}{T_{2}}
$$

$$
\frac{760 \mathrm{~mm} \mathrm{Hg} \times 600 \mathrm{~cm}^{3}}{298 \mathrm{~K}}=\frac{P_{2} \times 650 \mathrm{~cm}^{3}}{283 \mathrm{~K}}
$$

$$
P_{2}=666.2 \mathrm{mmHg}=88823 \mathrm{~Pa}=88.823 \mathrm{kPa}
$$

### 1.3 Dalton law of partial pressure

In most practical applications we encounter a mixture of gases rather than a single gas. The air we breathe has nitrogen and oxygen gases as major components and a variety of other gases in minute quantities. All of these gases contribute to the total atmospheric pressure.

Also, the pressure that a constituent gas of a mixture of gases would exert if it alone occupies the volume of the mixture at same temperature is defined as the partial pressure of that gas. A postulate introduced by Dalton says that the total pressure exerted by the mixture of non-reactive gases is equal to the sum of the partial pressures of individual gases. This is known as "Dalton law of partial pressures".

Accordingly, if partial pressures of individual gases in a mixture of gases A, B and C are $P_{A}, P_{B}$ and $P_{C}$ respectively, at constant temperature and constant volume the total pressure $\boldsymbol{P}_{\boldsymbol{T}}$ of the mixture is given by the following equation.

$$
P_{T}=P_{A}+P_{B}+P_{C}
$$

The Dalton law of partial pressure can be derived using ideal gas equation as follows. Consider a mixture of gases A and B with $n_{A}$ and $n_{B}$ moles, respectively exerting the total pressure of $P_{T}$.

$$
P V=n R T
$$

For gas A, $\quad n_{A}=P_{A} V / R T\left(\mathrm{P}_{\mathrm{A}}\right.$ is the partial pressure of gas A)
For gas $\mathrm{B}, \quad n_{B}=P_{B} V / R T \quad\left(\mathrm{P}_{\mathrm{B}}\right.$ is the partial pressure of gas B$)$
For the mixture of gases, $\quad n_{T}=P_{T} V / R T$
and

$$
\begin{array}{ll}
\text { and } & n_{T}=n_{A}+n_{B} \\
\text { Therefore, } & P_{T} V / R T=\left(P_{A} V / R T\right)+\left(P_{B} V / R T\right)
\end{array}
$$

Simplification gives, $\boldsymbol{P}_{\boldsymbol{T}}=\boldsymbol{P}_{\boldsymbol{A}}+\boldsymbol{P}_{\boldsymbol{B}}$
This is the Dalton law of partial pressures.

### 1.3.1 Partial pressure in terms of mole fraction

Suppose at the temperature $T, n_{A}$ moles of gas A and $n_{B}$ moles of gas B , are enclosed in a container of volume $V$, then partial pressures exerted by gases A and B are $P_{A}$ and $P_{B}$ respectively while the total pressure is $P_{T}$.

Therefore, we can write, $P_{A}=\frac{n_{A} R T}{V}$ and $P_{B}=\frac{n_{B} R T}{V}$
According to Dalton law, $P_{T}=P_{A}+P_{B}$
Substituting from the above, $P_{T}=\frac{n_{A} R T}{V}+\frac{n_{B} R T}{V}=\left(n_{A}+n_{B}\right) \frac{R T}{V}$
Dividing the expressions for $P_{A}$ and $P_{B}$ separately by $P_{T}$, we get;

$$
\frac{P_{A}}{P_{T}}=\frac{n_{A} R T / V}{\left(n_{A}+n_{B}\right) R T / V}=\frac{n_{A}}{\left(n_{A}+n_{B}\right)}=x_{A} \text { this is the mole fraction of } \mathrm{A}
$$

Likewise,

$$
\frac{P_{B}}{P_{T}}=\frac{n_{B} R T / V}{\left(n_{A}+n_{B}\right) R T / V}=\frac{n_{B}}{\left(n_{A}+n_{B}\right)}=x_{B}: \text { this is the mole fraction of } \mathrm{B}
$$

Therefore, we can write,

$$
P_{A}=x_{A} P_{T} \text { and } P_{B}=x_{B} P_{T}
$$

Partial pressure of the constituent gas is equal to the product of total pressure and mole fraction of the gas.

## Example 1.9

(i) A mixture of gases contains 0.8 mol of nitrogen gas $\left(\mathrm{N}_{2}\right)$ and 0.2 mol of oxygen $\left(\mathrm{O}_{2}\right)$. Calculate the partial pressures of the gases if the total pressure is 1.00 atm at a certain temperature.
(ii) When the container is heated and kept at a constant temperature, $\mathrm{N}_{2}$ gas is reacted with $\mathrm{O}_{2}$ gas to produce $\mathrm{NO}_{2}$ gas. At equilibrium the container has 0.7 mol of $\mathrm{N}_{2}$ gas, 0.15 mol of $\mathrm{O}_{2}$ gas and 0.1 mol of $\mathrm{NO}_{2}$ gas. If the partial pressure of $\mathrm{N}_{2}$ gas is now 0.88 atm , calculate partial pressures of $\mathrm{O}_{2}$ gas and $\mathrm{NO}_{2}$ gas.

## Answer

$X_{N_{2}}=\frac{n_{N_{2}}}{n_{N_{2}}+n_{O_{2}}}=\frac{0.8 \mathrm{~mol}}{0.8 \mathrm{~mol}+0.2 \mathrm{~mol}}=0.8$
$P_{N_{2}}=X_{N_{2}} P_{T}$
$P_{N_{2}}=0.8 \times 1.00 \mathrm{~atm}$
$P_{N_{2}}=0.8 \mathrm{~atm}$
Similarly for $\mathrm{O}_{2}$,
$P_{O_{2}}=0.2 \mathrm{~atm}$
(ii) $X_{N_{2}}=\frac{n_{N_{2}}}{n_{N_{2}}+n_{O_{2}}+n_{N_{2}}}$ therefore, $X_{N_{2}}=\frac{0.7 \mathrm{~mol}}{0.7 \mathrm{~mol}+0.15 \mathrm{~mol}+0.1 \mathrm{~mol}}=\frac{0.7}{0.95}$
$P_{N_{2}}=X_{N_{2}} P_{T}$ therefore, $P_{T}=P_{N_{2}} / X_{N_{2}}=\frac{0.88 \mathrm{~atm}}{0.7 / 0.95}=1.19 \mathrm{~atm}$
$X_{O_{2}}=\frac{n_{O_{2}}}{n_{N_{2}}+n_{O_{2}}+n_{N O_{2}}}$ therefore, $X_{O_{2}}=\frac{0.15 \mathrm{~mol}}{0.7 \mathrm{~mol}+0.15 \mathrm{~mol}+0.1 \mathrm{~mol}}=\frac{0.15}{0.95}$
$P_{O_{2}}=X_{O_{2}} P_{T}$ therefore, $P_{O_{2}}=\frac{0.15}{0.95} \times 1.19 \mathrm{~atm}=0.19 \mathrm{~atm}$
$X_{\mathrm{NO}_{2}}=\frac{n_{\mathrm{NO}_{2}}}{n_{N_{2}}+n_{\mathrm{O}_{2}}+n_{\mathrm{NO}_{2}}}$ therefore, $X_{\mathrm{NO}_{2}}=\frac{0.10 \mathrm{~mol}}{0.7 \mathrm{~mol}+0.15 \mathrm{~mol}+0.1 \mathrm{~mol}}=\frac{0.10}{0.95}$
$P_{\mathrm{NO}_{2}}=X_{\mathrm{NO}_{2}} P_{T}$ therefore, $P_{\mathrm{NO}_{2}}=\frac{0.10}{0.95} \times 1.19 \mathrm{~atm}=0.12 \mathrm{~atm}$
Therefore,
$P_{N_{2}}=0.88 \mathrm{~atm}, P_{O_{2}}=0.19 \mathrm{~atm}, P_{\mathrm{NO}_{2}}=0.12 \mathrm{~atm}$,
$P_{T}=1.19 \mathrm{~atm}$

We apply our knowledge on Dalton law for a mixture of gases assuming that they have the same properties as pure gases, provided that all gases in the mixture are ideal gases thus do not react chemically with each other. However, in practical situations such as chemical reactions involving gases, the procedure used to collect may introduce another gas. For example, a technique often used to collect gases from a chemical reaction is the displacement of water from an inverted container. In this method, a gas is collected in the container by bubbling the gas through a tube into a gas jar filled with water which is placed upside-down in a water trough. So that the gas push all the liquid out from the bottle when it is collected. Here, we assume that the gas does not dissolve in water and does not react with water. However; we do not get the gas which is in the pure state. Instead, the collected gas is a mixture of the gas generated by the reaction and some water vapour formed from evaporation. The amount of water vapour contained in the gas is most readily measured by the pressure it exerts at that temperature, called the saturated vapour pressure. Therefore, to determine the pressure exerted by a gas collected in this
way at a specific temperature, it is necessary to subtract the vapour pressure of water from the total pressure of the mixture. Then from the partial pressure of the gas and its volume and temperature, the ideal gas law can be used to calculate the amount of the gas collected. This is illustrated in example 1.10

## Example 1.10

Suppose we produce gaseous oxygen by heating $\mathrm{KClO}_{3}(\mathrm{~s})$ as shown in the following reaction:

$$
2 \mathrm{KClO}_{3}(\mathrm{~s}) \rightarrow 2 \mathrm{KCl}(\mathrm{~s})+3 \mathrm{O}_{2}(\mathrm{~g})
$$

$1.50 \mathrm{dm}^{3}$ of $\mathrm{O}_{2}$ gas is collected over water at $27.0^{\circ} \mathrm{C}$ and 760 torr. Saturated vapour pressure of water at $27.0^{\circ} \mathrm{C}$ is 26.7 torr.
Calculate the number of moles of $\mathrm{O}_{2}$ gas produced.

## Answer

According to Dalton law, we can write:

$$
\begin{aligned}
& P_{\text {total }}=P_{\text {oxygen }}+P_{\text {water }} \\
& \therefore P_{\text {oxygen }}=P_{\text {total }}-P_{\text {water }}=(760-26.7) \text { torr }=733.3 \text { torr }=97764 \mathrm{~Pa}
\end{aligned}
$$

Using the ideal gas equation:
$P V=n R T$ and $n=\frac{P V}{R T}=\frac{97764 \mathrm{~Pa} \times 1.5 \times 10^{-3} \mathrm{~m}^{3}}{8.314 \mathrm{~J} \mathrm{~K}^{-1} \mathrm{~mol}^{-1} \times 300 \mathrm{~K}}=0.058 \mathrm{~mol}$

### 1.4 Molecular kinetic theory of gases

In the above sections we have gone through and understood the laws related to gaseous state based on experimental observations (Boyle law, Charles law, etc.). By conducting such experiments we can understand how the particular system behaves under different conditions. Though, such observations are made from experiments we then have to know or understand why a system behaves that way. For example, gas laws help us to predict that pressure increases when we compress gases but we need to know what happens in the molecular level when a gas is compressed. Therefore, a theoretical model is needed to explain such events or questions where the theory should help us to understand observations. The theory that attempts to explain the behaviour of gases at the molecular level is known as "molecular kinetic theory".

### 1.4.1 Assumptions of the molecular kinetic theory of an ideal gas

- Gases are composed of widely separated large number of small particles (molecules or atoms).
Because the particles are widely separated, the actual volume of the particles is very small compared to the total volume occupied by the gas. Or in other words the actual volume of the molecules is negligible in comparison to the empty space
between them. This postulate correctly predicts that the volume occupied by a gas is much larger than that of a liquid or a solid, in which the particles are much closer together. Because gas particles are so widely separated, gases have relatively low densities compared to liquids and solids. This assumption explains high compressibility of gases.
- Each particle in a gas is in random (all possible directions), straight-line motion and undergoes perfectly elastic collisions with another particle or with the walls of the container. Different particles have different speeds.
Energy may be transferred from one particle to another, their individual energies may change, but there is no net loss or gain of energy. Pressure is exerted by the gas as a result of collision of the particles with the walls of the container.
- The average kinetic energy of gas particles depends only on the absolute temperature.
This tells us that the gas particle (molecule or atom) has its own mass and speed because the kinetic energy $(K E)$ for a given gas particle is given by the equation

$$
K E=\frac{1}{2} m v^{2}
$$

where $m$ is the mass of a gas particle and $v$ is the velocity (or speed). We can see that upon heating a gas at constant volume, the pressure increases. That is because, on heating the gas, kinetic energy of the particles increases and they strike the walls of the container more frequently thus exerting more pressure. As such the relation of kinetic energy of one mole of particle with the temperature is given by the following equation.

$$
K E=\frac{3}{2} R T
$$

Further, we can make following notes too.

- Particles of a gas behave independently of one another.

Because gas particles are widely separated, they move independently of one another unless they collide. That is, no forces of attraction or repulsion operate among gas particles. We can see that this postulate explains Dalton law of partial pressures. This postulate also explains why gases fill their containers entirely.

- The pressure of a gas arises from the sum of the collisions of the particles with the walls of the container.
This postulate explains Boyle law; at a given temperature, for the same amount of gas, the smaller the volume of the container and hence more collisions occur per unit area. The average distance traveled by a gas particle before a collision is less in a smaller volume. Therefore, more collisions occur in a given area producing greater pressure.

This assumption also predicts that pressure should be proportional to the number of moles of gas particles. The more gas particles, the greater the frequency of collisions with the walls, so the greater the pressure.

### 1.4.2 Equation of molecular kinetic theory

The equation below is named as the equation of molecular kinetic theory.

$$
P V=\frac{1}{3} m N \overline{c^{2}}
$$

This equation now gives pressure, a macroscopic quality, in terms of molecular motion. The significance of the above relationship is that pressure is proportional to the meansquare speed of molecules in a given container at a given temperature. From the equation we can see that when molecular speed increases the pressure exerted on the container increases. $\overline{c^{2}}$ is defined as the mean square speed of molecules.

### 1.4.3 Root mean square speed and mean speed

It is worth knowing the definitions of molecular speeds in different forms as follows: When $N$ number of molecules in a constant volume container at constant temperature travel with the different speeds of $c_{1}, c_{2}, \ldots c_{N}$, it can be written as shown below.

$$
\begin{aligned}
& \text { Average speed, } \bar{C}=\frac{c_{1}+c_{2}+\cdots c_{N}}{N} \\
& \text { Mean square speed } \overline{c^{2}}=\frac{\left(c_{1}^{2}+c_{2}^{2}+c_{3}^{2} \ldots+c_{N}^{2}\right)}{N} \\
& \text { Root mean square speed }=\sqrt{\overline{c^{2}}}
\end{aligned}
$$

Molecular kinetic equation can be used to derive equation to show temperature dependence of the mean square speed $\overline{c^{2}}$. Consider the equation for having N number of particles in volume $V$. We know that, $P=\frac{m N \overline{c^{2}}}{3 V}$ and we can write this as; $P V=\frac{m N \overline{c^{2}}}{3}$

Since, $N=n N_{A}$, where $N_{A}$ is the Avogadro's constant and $n$ is the number of moles;

$$
P V=\frac{1}{3} m n N_{A} \overline{c^{2}}
$$

Since, $M=m N_{A}$, then the above equation can be rearranged as, ( $M$ is the molar mass)

$$
P V=\frac{1}{3} n M \overline{c^{2}}
$$

Substitution of ideal gas law, $P V=n R T$ in the above equation gives,

$$
\begin{aligned}
n R T & =\frac{1}{3} M n \overline{c^{2}} \\
\overline{c^{2}} & =\frac{3 R T}{M}
\end{aligned}
$$

And hence we can write root mean square speed as;

$$
\sqrt{\overline{c^{2}}}=\sqrt{\frac{3 R T}{M}}
$$

## Example 1.11

Calculate the root mean square speed of $\mathrm{H}_{2}$ and $\mathrm{N}_{2}$ gases at $25^{\circ} \mathrm{C}$.

## Answer

$T=25^{\circ} \mathrm{C}=298 \mathrm{~K}$
$M\left(H_{2}\right)=2.0 \mathrm{~g} \mathrm{~mol}^{-1}=0.002 \mathrm{~kg} \mathrm{~mol}^{-1}$
$M\left(N_{2}\right)=28.0 \mathrm{~g} \mathrm{~mol}^{-1}=0.028 \mathrm{~kg} \mathrm{~mol}^{-1}$
$R=8.314 \mathrm{~J} \mathrm{~K}^{-1} \mathrm{~mol}^{-1}$

For $\mathrm{H}_{2}$
Substituting in $\sqrt{\overline{c^{2}}}=\sqrt{\frac{3 R T}{M}}=\sqrt{\frac{3 \times 8.314 \mathrm{~J} \mathrm{~K}^{-1} \mathrm{~mol}^{-1} \times 298 \mathrm{~K}}{0.002 \mathrm{~kg} \mathrm{~mol}^{-1}}}=1927.8 \mathrm{~m} \mathrm{~s}^{-1}$
For $\mathrm{N}_{2}$
Substituting in $\sqrt{\overline{c^{2}}}=\sqrt{\frac{3 R T}{M}}=\sqrt{\frac{3 \times 8.314 \mathrm{~J} \mathrm{~K}^{-1} \mathrm{~mol}^{-1} \times 298 \mathrm{~K}}{0.028 \mathrm{~kg} \mathrm{~mol}^{-1}}}=515.2 \mathrm{~m} \mathrm{~s}^{-1}$

From the above example, we can see that heavier molecules move slowly at a given temperature implying that the molecules having higher mass do not have to move as rapidly as lighter molecules to have the same kinetic energy. This kinetic energy directly related to temperature and this can be proved based on the equation of molecular kinetic theory as follows.

We have, $P V=\frac{m N \overline{c^{2}}}{3}$

Multiply the above equation by 2 and also divide by 2 , then we can rearrange the equation
as;

$$
\begin{gathered}
P V=\frac{m N \overline{c^{2}}}{3}=\frac{2 N}{3}\left(\frac{1}{2} m \overline{c^{2}}\right)=n R T \\
N\left(\frac{1}{2} m \overline{c^{2}}\right)=\frac{3}{2} n R T
\end{gathered}
$$

And also we can write $\left(\frac{1}{2} m \overline{c^{2}}\right)=\frac{3}{2}\left(\frac{R n}{N}\right) T=\frac{3}{2}\left(\frac{R}{N_{A}}\right) T=\frac{3}{2}\left(k_{B}\right) T$
$k_{B}$ is the Boltzmann constant.
We can then write these as $\frac{1}{2} m \overline{c^{2}}$ is the kinetic energy (KE)

$$
\begin{gathered}
\boldsymbol{K} \boldsymbol{E}=\frac{3}{2} \boldsymbol{k}_{\boldsymbol{B}} \boldsymbol{T} \text { (per molecule) } \\
K E=\frac{3}{2}\left(k_{B}\right) T N_{A} \\
K E=\frac{3}{2}\left(\frac{R}{N_{A}}\right) T N_{A} \\
\boldsymbol{K} \boldsymbol{E}=\frac{\mathbf{3}}{\mathbf{2}} \boldsymbol{R} \boldsymbol{T} \text { (per mole) }
\end{gathered}
$$

This proves that the kinetic energy of a gas depends only on the Kelvin temperature.

### 1.4.4 Maxwell- Boltzmann distribution

Although from the above example we have calculated speed of $\mathrm{N}_{2}$ molecule as $515 \mathrm{~m} \mathrm{~s}^{-1}$, it does not mean that all the $\mathrm{N}_{2}$ molecules travel at this speed (as the molecules move in straight line directions, that the motion has vector properties, such that the molecular speeds are expressed in relation). There is a distribution of speeds from zero to values considerably above $515 \mathrm{~m} \mathrm{~s}^{-1}$. This is because as individual molecules collide and exchange energy, their speeds vary. This speed distribution can be shown as a fraction of molecules travelling with particular speeds as shown in Figure 1.6 and such a distribution is called Maxwell- Boltzmann distribution of speeds.

Figure 1.6 (a) Maxwell- Boltzmann speed distribution for nitrogen gas at different temperatures (b) Speed distribution of three gases at 300 K

### 1.5 Amendments to ideal gas equation to apply for real gases

For a one mole of an ideal gas we can write $P V=R T$ or in other words $\frac{P V}{R T}=1$ at a given temperature. When we have a real gas it actually deviates from ideal behaviour to some extent. The quantity, $Z=\frac{P V}{R T}$, called compressibility factor (coefficient) is used as one of the measures of this deviation. For example, for a one mole of an ideal gas if we study or analyze the variation of $Z$ with pressure at constant temperature, $P V$ will be constant (Boyle law) and $Z$ vs $P$ graph at all pressures will be a straight line parallel to $x$-axis (pressure - axis). Figure 1.7(a) shows such a plot for several gases at 273 K and Figure 1.7(b) for a one gas at several temperatures.

Figure 1.7 Variation of compressibility factor for several gases with the comparison of an ideal gas. (a) The variation of $Z$ with pressure at a constant temperature. Inset in (a) shows the Boyle law plot for ideal gas and real gas. (b) is the variation of $Z$ with pressure at different temperatures for $\mathrm{CH}_{4}$ gas.

From the plots shown in Figure 1.7 (a) it can be seen easily that at constant temperature $\frac{P V}{R T} v s P(Z v s P)$ plots for real gases is not a straight line parallel to the $x$-axis (pressure). There is a significant deviation from ideal behaviour. For different types of real gases, two types of curves are resulted. In the curves for hydrogen and helium, the value of $Z$ increases as the pressure increases. The second type of plot is seen in the case of other gases like carbon monoxide ( CO ) and methane $\left(\mathrm{CH}_{4}\right)$. In these plots first there is a negative deviation from ideal behavior, the $Z$ value decreases with increase in pressure and reaches to a minimum value characteristic of a gas. After that it starts increasing, crosses the line for ideal gas and increases continuously showing a positive deviation. With these observations it can be found that real gases do not follow ideal gas equation perfectly under all conditions.

This deviation from ideal behaviour can also be understood when pressure versus volume plot is considered which is drawn as an inset in the Figure 1.7(a). In that plot the pressure versus volume data of a real gas is compared with those calculated theoretically. We know that this is the plot of Boyle law (for an ideal gas) and if the real gas follows the same behaviour two plots should coincide. It is clearly apparent that at very high pressures the measured volume is more than the calculated volume and at low pressures, measured and calculated volumes approach close to each other indicating further that low pressure conditions favour the ideal behavior. Thus gases show ideal behavior when the volume occupied is large so that the volume of the molecules can be neglected in comparison to the volume of the container. In other words, the behaviour of the real gas becomes more ideal when pressure is very low and depends upon the nature of the gas and its temperature.

We can further interpret the above behaviour of real gases where Z is less than $1(\mathrm{Z}<1)$ as a combination of intermolecular interactions and repulsions caused by the significant sizes of the molecules when they become crowded at high pressures. At low pressures but still high for the ideal behaviour intermolecular attractions lower the molar volume and Z value is less than 1 . At sufficiently high pressures, molecules tend to become crowded and the volume of the gas particles become large compared to the situation when it would be a point mass. At high temperature (Figure 1.7(b)) intermolecular attractions become less and $P V$ factor increases making $Z$ values greater than one $(Z>1)$. However deviation from the ideal line is less indicating that the higher temperatures favour the ideality to some extent. Therefore, we can say very low pressures and high temperatures are the favourable conditions for the ideal behaviour of real gases.

If we compare this behaviour of real gases with ideal gases considering these variations in molar volume at a given temperature and pressure, then the relation of compressibility factor Z may be understood. Assume that one mole of a real gas has the volume $V_{\text {real }}$ and that for the ideal gas as $V_{\text {ideal }}$. Therefore, we can write;

$$
Z=\frac{P V_{\text {real }}}{R T}
$$

If the gas shows ideal behaviour under the same conditions;

$$
P V_{\text {ideal }}=R T(\text { per one mole })
$$

Substituting this in the first equation we get; $Z=\frac{P V_{\text {real }}}{P V_{\text {ideal }}}$
Therefore, $Z=\frac{V_{\text {real }}}{V_{\text {ideal }}}$

Therefore, we can see that the compressibility factor $Z$ is the ratio of actual molar volume of a gas to the molar volume of it if it behaves as an ideal gas at that temperature and pressure.

Based on this kinds of experiments, it has been found that real gases do not follow Boyle law, Charles law and Avogadro law perfectly under all conditions. Therefore we have to understand; why gases deviate from the ideal behaviour and the conditions under which gases deviate from ideal behaviour.

For the first one we can use the assumptions made in the molecular kinetic theory where it was assumed that; there is no force of attraction between the molecules of a gas and volume of the molecules of a gas is negligibly small in comparison to the space occupied by the gas.

If there are no interactions among gas molecules, the gas will never liquefy. However, we know that gases do liquefy when cooled and compressed. Once the gases are cooled and compressed the gas molecules will come close and then form liquids. If the volume of a gas molecule is negligible then the pressure versus volume graph of real gas and that of an ideal gas should coincide (see the inset of Figure 1.7 (a) and the behavior shown in the inset help us to understand the deviation of real gases from ideality). But it does not happen therefore, the real gases deviate from ideality.

### 1.5.1 van der Waals equation

At the beginning of this unit, an ideal gas law, $P V=n R T$ known as equation of state was used to understand the behaviour of gases under different conditions with the measurable variables of $P, V, T$ and $n$. From the above clarifications it can be understood that real gases show deviations from the ideal gas law due to the interactions among molecules and a significant volume of a gas molecule. Therefore, it is necessary to have another kind of equations of state to describe the behaviour of real gases as the measured pressures and volumes would not be the same as those for an ideal gas. Dutch physicist, J. D. van der Waals suggested the following which relates pressure and volume of a real gas to the pressure and volume of an ideal gas.

At high pressures molecules of gases are very close to each other and molecular interactions start to operate. Therefore, at high pressures, molecules cannot strike on the walls of the container with full force of impact as these are dragged back by other molecules due to the operation of these molecular attractive forces (a sketch on this behaviour is shown in Figure 1.8 comparing with an ideal gas). This affects the pressure exerted by the molecules on the walls of the container. Thus, the pressure exerted by the real gas is lower than the pressure exerted by the ideal gas under similar conditions.

(a)

(b)

Figure 1.8 Comparison of the impact on the wall due to the collision of (a) an ideal gas molecule and (b) a real gas molecule.

As shown in the above figure reduction of pressure of a real gas is due to the intermolecular attractions. As it was found that the number of collisions with the wall in a given time is proportional to the density of the gas, the correction factor to pressure is proportional to the square of the gas amount and inversely proportional to the square of the volume and then the correction factor can be written as $\frac{a n^{2}}{V^{2}}$ where $a$ is a constant related to magnitude of attractive forces and is independent of temperature and pressure. $n$ and $V$ are the number of moles of the gas and volume of the container respectively. Therefore, the pressure of the system under this condition is given by the following expression.

$$
P_{\text {ideal }}=P_{\text {real }}+\frac{a n^{2}}{V^{2}}
$$

At high pressure, repulsive forces are significant as molecules are almost in contact. Therefore, these repulsive forces cause the molecules to behave as small spheres to minimize the effect and hence results a significant volume occupied by the molecules. Now the ideal volume should be less than the measured volume because instead of moving in volume $V$, these are now restricted to an effective volume of

$$
(V-n b)
$$

$n b$ is approximately the total volume occupied by the molecules themselves and $b$ is a constant (volume of one molecule). Having taken into account the corrections for pressure and volume, we can rewrite the equation $P V=n R T$ as,

$$
\left(P+\frac{a n^{2}}{V^{2}}\right)(V-n b)=n R T
$$

This is called van-der Waals equation and $a$ and $b$ are called van-der Waals constants. If we write this equation for one mole of a real gas it takes the following form.

$$
\left(P+\frac{a}{V^{2}}\right)(V-b)=R T
$$

### 1.5.2 Critical temperature and liquefaction of gases

At the beginning of the chapter the importance of the extent of the intermolecular forces to maintain a particular physical state was discussed. Matter can be interconverted between physical states supplying heat or cooling as needed to change the intermolecular distance.

For example, we may think that liquefaction of a gas can be done just by cooling and compression. Though it is correct to some extent, we need more ideas about the behaviour of real gases in accordance with their phase changes.

Note: This is one of the topics discussed in detail in unit 12 and a little description will be given here as it is important to have a basic idea about the conditions necessary for liquefication of gases.

For example, such kind of information on the pressure, temperature and volume relations are available for carbon dioxide where it has been found that carbon dioxide can behave as a gas, a liquid and a solid depending on the variations in pressure and temperature.

We know that high temperatures favour the ideal behaviour and a gas cannot be liquefied even at very high pressures. In the case of carbon dioxide, which exists as a gas at high temperatures starts to liquefy at $30.98^{\circ} \mathrm{C}(304.2 \mathrm{~K})$ when the pressure is below 73 atm . The temperature $30.98^{\circ} \mathrm{C}$ is called critical temperature ( $\boldsymbol{T}_{\mathrm{C}}$ ) of carbon dioxide. This is the highest temperature at which liquid carbon dioxide is observed and above this temperature it exists only as a gas. Therefore, we can defined the critical temperature of a substance as the temperature at and above which the vapour of the substance cannot be liquefied, no matter how much pressure is applied. The critical pressure of a substance is the pressure required to liquefy a vapour at critical temperature.

Figure 1.9 Phase diagram of $\mathrm{CO}_{2}$

Table 1.3 A summary of equations

| Gas law | Equation | Parameters kept <br> constant |
| :--- | :--- | :--- |
| Ideal gas law | $P V=n R T$ | None |
| Boyle law | $P=k / V$ | n and T |
| Charles law | $V=k T$ | n and P |
| Avogadro law | If $V_{A}=V_{B}$ then $N_{A}=N_{B}$ | P and T |
| Molecular kinetic <br> equation | $P V=\frac{1}{3} m N \overline{c^{2}}$ |  |
| Average speed | $\bar{C}=\frac{c_{1}+c_{2}+\cdots c_{N}}{N}$ |  |
| Mean square speed | $\overline{c^{2}}=\frac{\left(c_{1}{ }^{2}+c_{2}{ }^{2}+c_{3}{ }^{2} \ldots .+c_{N}{ }^{2}\right)}{N}$ |  |
| Mean square speed | $\overline{c^{2}}=\frac{3 R T}{M}$ | for one mole of gas |
| Dalton law of partial <br> pressures | $P_{A}=x_{A} P_{T}$ |  |
| $P_{T}=P_{A}+P_{B}+P_{C}$ |  |  |
| Compressibility <br> factor | $z=\frac{P V}{R T}$ | $\left(P+\frac{a n^{2}}{V^{2}}\right)(V-n b)=n R T$ |

- Standard enthalpy change of electron gain, $\Delta H_{E G}^{\Theta}$
- Standard lattice enthalpy change of an ionic compound, $\Delta H_{L}^{\ominus}$
2.2.5 Indirect determination of $\Delta H\left(\Delta H^{\ominus}\right)$ : Hess law
- Standard enthalpy of reaction
2.3 Lattice enthalpy or enthalpy of formation of an ionic compound: BornHaber cycle

### 2.4 Spontaneity of chemical reactions

- Standard entropy change of a chemical reaction
- Gibbs free energy $(G)$ and spontaneity of a reaction

## Introduction

This unit discusses the study of the role or changes of energy in the form of heat. Almost all chemical reactions absorb or release energy, generally in the form of heat. It is important to understand the distinction between thermal energy and heat. Heat is the transfer of thermal energy between two bodies that are at different temperatures and we often speak of "heat flow" from a hot object to a cold one. Although the term "heat" by itself implies transfer of energy when describing the energy changes that occur during a process, we customarily talk of "heat absorbed" or "heat released". Thermochemistry is the study of heat change in chemical reactions and when considering thermochemical events they are usually in reference to a state of standard state.

This chapter is concerned with the study of energy changes at the molecular level and the consequences to the changes of that system. In this regard, the basic terms appearing in thermochemistry must first be defined and understood. The significance of mathematical symbols " + " and " - " specified with the energy change must also be understood in respect of the amount of energy produced or supplied and this will be used to explain types of reactions such as endothermic and exothermic reactions. Thereafter, the discussion will move into the definition of enthalpies of different chemical events/reactions and expanded to the standard state. The basic laws in thermochemistry (Hess Law) will be used to perform calculations for chemical events as appropriate. Finally, the tendency for the occurrence of a reaction will be discussed with entropy, enthalpy and Gibbs free energy relation ( $\Delta G=\Delta H-T \Delta S$ ) and hence to the spontaneity of reactions.

### 2.1 Basic terms in thermochemistry and thermodynamics

### 2.1.1 System, surrounding and boundary

It is useful to define and understand important terms that are used to define and explain the basic concepts and laws of thermochemistry.

## - System

A thermochemical system is defined as any portion of matter or universe under consideration which is separated from the rest of the universe. (or simply the object under study is defined as the system).

## - Surroundings

Everything in the universe (or the rest) that is not a part of the system and can interact with it is called surroundings (or simply everything outside the system).

## - Boundary

It is anything (for example wall of flask) which separates the system from its surroundings.

Figure 2.1 Schematic representation of a system, surroundings and boundary

### 2.1.2 Types of systems

There are different types of systems which can be defined depending on the interactions/processes between the system and the surroundings.

## - Open system

A system is said to be open if it can exchange both energy and matter/ mass with its surroundings. For example, an open bottle containing an aqueous salt solution represents an open system. Here, matter and heat can be added or removed simultaneously or separately from the system to its surroundings or separately from the surroundings to the system.

## - Closed system

A system which permits the exchange of energy but not matter/ mass, across the boundary with its surroundings is called a closed system. For example, a liquid in equilibrium with its vapour in a sealed bottle represents a closed system since the sealed container may be heated or cooled to add or remove energy from its contents while no matter (liquid or vapour) can be added or removed.

## - Isolated system

A system which can exchange neither energy nor matter with its surroundings is called an isolated system. For example, a sample in a sealed thermos flask with walls made of insulating materials represents an isolated system.

Figure 2.2 Schematic view of (a) open, (b) closed and (c) isolated systems

## - Homogeneous and heterogeneous systems

A system is said to be homogeneous if the physical states of all its matter are uniform. For example mixtures of gases, mixtures of completely miscible liquids, etc.

## G.C.E. (A/L) CHEMISTRY : UNIT 5 Energetics

A system is said to be heterogeneous, if its contents do not possess the same physical state (phase). For example, immiscible liquids, solid in contact with an immiscible liquid, solid in contact with a gas, etc.

### 2.1.3 Properties of a system

## - Microscopic properties

A system is called a microscopic system if it is roughly of atomic dimensions i.e. on the atomic or molecular scale the properties must be determined by an indirect method(s) such as kinetic energy, speed, etc. of atoms/molecules in a closed container.

- Macroscopic properties

The properties which are associated with bulk or macroscopic state of the system such as pressure, volume, temperature, concentration, density, viscosity, surface tension, refractive index, colour, etc. are called macroscopic properties.

Macroscopic properties of a system can be divided into two types.

- Extensive properties

The properties that depend on the amount or size of a system (extent of a system) are called extensive properties. (For example, volume, number of moles, mass, energy, internal energy etc.). The value of the extensive property is equal to the sum of extensive properties of smaller parts into which the system is divided. Suppose masses $\mathbf{m}_{1} \mathrm{~g}, \mathbf{m}_{\mathbf{2}} \mathrm{g}$ and $\mathbf{m}_{3} \mathrm{~g}$ are mixed in a system. Then the total mass of the system is equal to $\left(\mathbf{m}_{1}+\mathbf{m}_{\mathbf{2}}+\mathbf{m}_{\mathbf{3}}\right) \mathrm{g}$. Thus mass is an extensive property.

## - Intensive properties

The properties that are independent of the amount or size of the system (extent of a system) are known as intensive properties. (For example, refractive index, surface tension, density, temperature, boiling point, freezing point, etc.), of the system. These properties do not depend on the number of moles of the substance in the system.

If any extensive property is expressed per mole $\left(\mathrm{mol}^{-1}\right)$ or per gram $\left(\mathrm{g}^{-1}\right)$ or per $\mathrm{cm}^{3}\left(\mathrm{~cm}^{-3}\right)$ or per $\mathrm{cm}^{2}\left(\mathrm{~cm}^{-2}\right)$, it becomes an intensive property. For example, mass, volume, heat capacity are extensive properties while density, molar volume, specific heat capacity are intensive properties.

### 2.1.4 State of a system

A system is said to be in a particular physical state when specific values of the macroscopic properties of the system are known. For example, the gaseous state of matter can be described by parameters pressure ( P ), volume ( V ) and temperature ( T ) etc. The values of these parameters change when the matter is in liquid state. Thus, the
state of a system is defined by specific measurable macroscopic properties of the system.

The initial state of system refers to the starting state of the system before any kind of interaction with its surroundings.

The final state of system refers to the state after the interaction of system with its surroundings. A system can interact with its surroundings by means of exchange of matter, heat, energy or all.

The variables like $\mathrm{P}, \mathrm{V}, \mathrm{T}$ and composition (or amount of moles or ' $n$ ') that are used to describe the state of a system are called state variables or state functions. When the state of the system changes, the values of the state variables of the system also change. Thus, state functions depend only on the initial state and the final state of the system and not on how the changes occur. Also, if the values of state functions of a system are known, all other properties like mass, viscosity, density, etc. of the system become specified. For specifying a state of the system, it is not necessary to know all the state variables, since they are interdependent and only a few of them (state variables) are sufficient.

## Standard state

It is needed to refer to a reference pressure or the standard pressure denoted by $P^{\theta}$ at a specified temperature when heat changes in a system is considered. The standard pressure has a constant value in any given application. The IUPAC recommended the value for $P^{\theta}$ as 1 atm (101325 Pa). (Note that there is no defined standard temperature, however, 298 K is used sometimes as specified.) A standard state of a pure substance is a particular reference state appropriate for the phase and is described by intensive variables. For example, standard state of solid iron is pure iron at 1 atm and at a given temperature ( 500 K ). Standard conditions are denoted by adding the superscript $\theta$ to the symbol of the quantity $\left(\Delta H^{\ominus}\right.$, $\Delta G^{\ominus}, \Delta S^{\ominus}$ etc.) It has to be noted that when solutions are involved, a concentration is $1 \mathrm{~mol} \mathrm{dm}{ }^{-3}$.

## - Spontaneous processes

These are occurring on their own accord. For example heat flow from a hotter end of a metal rod to a colder end. In these processes, the transformation of the system from the initial, to the final state is favourable in a particular direction only. Many of the spontaneous processes are natural processes and are also, irreversible processes.

## - Non-spontaneous processes

These are not occurring on their own accord. For example, although carbon burns in air evolving heat to form carbon dioxide, on its own carbon does not catch fire and an initial heat supply is required.

## - Reversible process

In a reversible process the series of changes carried out on the system during its transformation from initial to final state may be possibly reversed in an exact manner. This is possible when the changes are carried out very slowly in many smaller steps on the system during its change from initial to final state. Under such conditions the initial and final states of the system become reversible completely. For example, when ice melts a certain amount of heat is absorbed. The water formed can be converted back to ice if the same amount of heat is removed from it.

- Irreversible process

An irreversible process is one which cannot be retraced to the initial state without making a permanent change in the surroundings. Many of the spontaneous processes are irreversible in nature. For example biological ageing is an irreversible process. Water flowing down a hill on its own accord is an irreversible process.

### 2.1.5 Enthalpy (H)

Most of the physical and chemical changes take place or are carried out under the constant pressure conditions. For example in the laboratory, reactions are generally carried out in beakers, flasks, or test tubes that remain open to their surroundings and hence to a pressure of approximately one atmosphere ( $1 \mathrm{~atm}, \sim 10^{5} \mathrm{~Pa}$ ). To quantify the heat flow into or out of a system in a constant pressure process, chemists use a property called enthalpy, represented by the symbol $\boldsymbol{H}$. i.e. at constant pressure chemist use the relation, heat change equals to enthalpy change. Enthalpy is an extensive property; its magnitude depends on the amount of the substance present. It is impossible to determine the enthalpy of a substance, so it is the change in enthalpy, $\Delta \mathrm{H}$, that we actually measure.

The enthalpy change of reaction, $\Delta \boldsymbol{H}$, is the difference between the total enthalpies of the products and the total enthalpies of the reactants.

$$
\Delta H=H_{\text {(products) }}-H_{\text {(reactants) }}
$$

### 2.1.6 Heat

As the enthalpy is equal to the heat $(q)$ at constant pressure, we may consider the measurement of heat changes. In the laboratory heat changes in physical and chemical processes are measured with a calorimeter, a closed container designed specifically for this purpose. To estimate heat changes we first need to have an understanding of specific heat and heat capacity.

## Specific heat and heat capacity

The specific heat (c) of a substance is the amount of heat required to raise the temperature of one gram of the substance by one degree Celsius. The heat capacity ( $C$ ) of a substance is the amount of heat required to raise the temperature of a given quantity of the substance by one degree Celsius. Specific heat is an intensive property, whereas heat capacity is an extensive property. The relationship between the heat capacity and specific heat of a substance is

$$
C=m c
$$

where, $m$ is the mass of the substance in grams.
Note: sometimes s is used to denote specific heat.
For example, the specific heat of water is $4.184 \mathrm{~J} \mathrm{~g}^{-1}{ }^{\circ} \mathrm{C}^{-1}$ and the heat capacity of 100.0 g of water is $(100.0 \mathrm{~g}) \times\left(4.184 \mathrm{~J} \mathrm{~g}^{-1}{ }^{\circ} \mathrm{C}^{-1}\right)=418.4 \mathrm{~J}^{\circ} \mathrm{C}^{-1}$.

Note: Specific heat has the units $\mathrm{J} \mathrm{g}^{-1}{ }^{\circ} \mathrm{C}^{-1}\left(\right.$ or $\left.\mathrm{J} \mathrm{g}^{-1} \mathrm{~K}^{-1}\right)$ and heat capacity has the units $\mathrm{J}^{\circ} \mathrm{C}^{-1}\left(o r \mathrm{~J} \mathrm{~K} \mathrm{~K}^{-1}\right)$.

Knowing the specific heat, the mass of a substance and the change in the sample's temperature $\Delta t$ (temperature in ${ }^{\circ} \mathrm{C}$ ) or $\Delta T$ (temperature in K ), the amount of heat ( $Q$ ) that has been absorbed or released in a particular process can be calculated by the equation;

$$
Q=m c \Delta t \quad \text { or } \quad Q=m c \Delta T
$$

where $m$ is the mass of the sample and $\Delta t$ is the temperature change i.e. $\Delta t=t_{\text {final }}-t_{\text {initial }}$ The sign convention for $q$ is the same as that for enthalpy change; $q$ is positive for endothermic processes and negative for exothermic processes.

### 2.2 Enthalpy changes and standard enthalpy changes associated with different thermochemical processes/ reactions

$\Delta H$ represents the heat given off or absorbed during a reaction. The enthalpy of reaction can be positive or negative, depending on the process. Enthalpy change is directly proportional to the amounts of substances in a system.

### 2.2.1 Exothermic and endothermic processes

When a thermodynamic process is a chemical reaction or a physical transformation, it is classified as either exothermic or endothermic depending on the nature of heat change involved in the overall process. These two processes are differentiated as follows:

Table 2.1 Comparison between endothermic and exothermic processes

| Endothermic processes | Exothermic processes |
| :---: | :---: |
| A process that transforms a system from initial to final state by absorption of heat is called an endothermic process. | A process that transforms a system from initial to final state by evolution of heat is called an exothermic process. |
| The final state of the system possesses higher energy than the initial state. The energy needed is absorbed as heat by the system from the surroundings. <br> Example: Dissolving ammonium chloride in water. | The final state of the system possesses lower energy than the initial state. The excess energy is released as heat to the surrounding. Example: All combustion processes are exothermic. |
| Generally in a physical transformation which is endothermic, heat is supplied to bring about the change from initial to final state. Example: melting of a solid by supplying heat is an endothermic process. | If the physical transformation is exothermic heat is removed to bring about the change from the initial to final state. Example: Freezing of a liquid at its freezing point is an exothermic process. |
| $\begin{aligned} & \text { Reactant + Energy(Heat) } \rightarrow \text { Products } \\ & \frac{1}{2} \mathrm{~N}_{2}(\mathrm{~g})+\frac{1}{2} \mathrm{O}_{2}(\mathrm{~g})+90 \mathrm{~kJ} \rightarrow \mathrm{NO}(\mathrm{~g}) \end{aligned}$ | Reactant $\rightarrow$ Products + Energy(Heat) $\mathrm{H}_{2}(\mathrm{~g})+\frac{1}{2} \mathrm{O}_{2}(\mathrm{~g}) \rightarrow \mathrm{H}_{2} \mathrm{O}(\mathrm{~g})+242 \mathrm{~kJ}$ |
| Surroundings <br> Heat System | Surroundings <br> System <br> Heat <br> H |
| For an endothermic process (heat absorbed by the system from the surroundings), $\Delta H$ is positive (that is, $\Delta H>0$ ) | For an exothermic process (heat released by the system to the surroundings), $\Delta H$ is negative (that is, $\Delta H<0$ ) |
|  |  |

Heat effects measured at constant pressure indicate changes in enthalpy of a system. Using calorimeters operating at constant pressure, the enthalpy change of a process can be measured directly.

## Standard enthalpy changes

The measured enthalpy change for a reaction has a unique value only if the initial state (reactants) and final state (products) are precisely described. If we define a standard state ( $10^{5} \mathrm{~Pa}$ pressure and a temperature of interest) for the reactants and products, we can then say that the standard enthalpy change is the enthalpy change in a reaction in which the reactants and products are in their standard states. This so-called standard enthalpy of reaction is denoted with a degree symbol, $\Delta H^{\theta}$. Although temperature is not a part of the definition of a standard state, it still must be specified in tabulated values because it depends on temperature. The standard temperature values given in this text are all 298.15 K or $25^{\circ} \mathrm{C}$ unless otherwise stated.
Simply, we can say;
The standard enthalpy change of a reaction is the enthalpy change which occurs when the given quantities in a reaction react under standard conditions to form products in the standard state.

### 2.2.2 Thermochemical equations

A balanced chemical equation together with standard conventions adopted and including the value of $\Delta H$ ( or $\Delta H^{\theta}$ ) of the reaction is called a thermochemical equation. The following conventions are necessarily adopted in a thermochemical equation.
(i) The coefficients in a balanced thermochemical equation refer to number of moles of reactants and products involved in the reaction.
(ii) The enthalpy change of a reaction has unit $\mathbf{k J ~ m o l}{ }^{-1}$ and will remain as it is, even if more than one mole of the reactant or product are involved but with only the magnitude changing.
(iii) When a chemical reaction is reversed the value of $\Delta H$ is reversed in sign with the magnitude remaining the same.
(iv) Physical states of all species is important and must be specified in a thermochemical equation since $\Delta H$ (or $\Delta H^{\theta}$ ) depends on states (phases) of reactants and products.
(v) If the thermochemical equation is multiplied throughout by a number, the enthalpy change is also be multiplied by the same number.
(vi) The negative sign of $\Delta H^{\theta}$ indicates an exothermic reaction and a positive sign of $\Delta H^{\theta}$ indicates an endothermic reaction.

## Example:

Consider the following reactions.

$$
\begin{array}{ll}
2 \mathrm{H}_{2}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \rightarrow 2 \mathrm{H}_{2} \mathrm{O}(\mathrm{~g}) & \Delta \boldsymbol{H}^{\ominus}=-\mathbf{4 8 3 . 7} \mathbf{~ k J ~ m o l}^{-1} \\
2 \mathrm{H}_{2}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \rightarrow 2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) & \Delta \boldsymbol{H}^{\ominus}=-\mathbf{5 7 1 . 6} \mathrm{kJ} \mathrm{~mol}^{-1}
\end{array}
$$

First reaction in the above thermochemical equations can be interpreted in several ways.

- 483.7 kJ given off per mole of the reaction*
- 483.7 kJ given off per 2 moles of $\mathrm{H}_{2}(\mathrm{~g})$ consumed
- 483.7 kJ given off per mole of $\mathrm{O}_{2}(\mathrm{~g})$ consumed

## G.C.E. (A/L) CHEMISTRY : UNIT 5 Energetics

- 483.7 kJ given off per 2 moles of water vapour formed
$\Delta H^{\theta}$ tells how much the enthalpy change would be, if the number of moles reacting is the same as the stoichiometric coefficients.
* Note: In this case, $483.7 \mathrm{~kJ} \mathrm{~mol}^{-1}$ means that 483.7 kJ of heat is evolved when 2 moles of hydrogen gas were to react with 1 mole of oxygen gas to form 2 moles of gaseous water

Sometimes the above reaction is written as;

$$
2 \mathrm{H}_{2}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \rightarrow 2 \mathrm{H}_{2} \mathrm{O}(\mathrm{~g}) \quad \Delta \boldsymbol{H}^{\ominus}=-483.7 \mathrm{~kJ}
$$

* Note: In this case, 483.7 kJ of heat is evolved when a defined extent of reaction occurs as written and gives the units in $\mathbf{k J}$. Extent of reaction has the unit of mol. For the above reaction ; $\Delta \boldsymbol{H}=\Delta \boldsymbol{H}^{\theta} \times \mathbf{m o l}=-483.7 \mathrm{~kJ} \mathrm{~mol}^{-1} \times \mathbf{m o l}=-483.7 \mathrm{~kJ}$

For example if we write the reaction as;

$$
4 \mathrm{H}_{2}(\mathrm{~g})+2 \mathrm{O}_{2}(\mathrm{~g}) \rightarrow 4 \mathrm{H}_{2} \mathrm{O}(\mathrm{~g})
$$

then we write $\Delta H$ of the reaction as $2 \times \Delta H^{\theta}=\mathbf{- 9 6 7 . 4} \mathbf{~ k J}$
That means the original $\Delta H^{\theta}$ value has to be multiplied by 2 or in other words the value of $\Delta H$ is multiplied by the amount (mol) of substance reacting. Therefore, instead of the extent of reaction, we can use the actual amount of substance of any species reacting, divided by its stoichiometric coefficient in the simplest balanced chemical equation. Hence for the above reaction we get (for oxygen),

$$
\Delta H=-483.7 \mathrm{~kJ} \mathrm{~mol}^{-1} \times\left(\frac{2 \mathrm{~mol}}{1}\right)=-967.4 \mathrm{~kJ}
$$

If we are giving only $\Delta H^{\ominus}$, then it would equals to $-967.4 \mathrm{~kJ} \mathrm{~mol}^{-1}$
If we write the equations as;

$$
\begin{array}{ll}
\mathrm{H}_{2}(\mathrm{~g})+\frac{1}{2} \mathrm{O}_{2}(\mathrm{~g}) \rightarrow \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) & \Delta \boldsymbol{H}_{f}^{\ominus}=-285.8 \mathbf{k J ~ m o l}^{-\mathbf{1}} \\
\mathrm{H}_{2}(\mathrm{~g})+\frac{1}{2} \mathrm{O}_{2}(\mathrm{~g}) \rightarrow \mathrm{H}_{2} \mathrm{O}(\mathrm{~g}) & \Delta \boldsymbol{H}_{f}^{\ominus}=-241.85 \mathbf{k J ~ m o l}^{-1}
\end{array}
$$

We can see that the enthalpy values are halves of the above values.
The above equations describe the combustion of hydrogen gas to water in a general sense. The first reaction can be considered the formation reaction of liquid water and the second reaction the formation of water vapour. The negative sign of $\Delta H$ indicates that they are exothermic reactions.

The reaction which is exothermic in the forward direction is endothermic in the reverse direction and vice-versa. This rule applies to both physical and chemical processes.

$$
\begin{array}{ll}
2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightarrow 2 \mathrm{H}_{2}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) & \Delta \boldsymbol{H}^{\ominus}=+571.6 \mathrm{~kJ} \mathrm{~mol}^{-1} \\
2 \mathrm{H}_{2} \mathrm{O}(\mathrm{~g}) \rightarrow 2 \mathrm{H}_{2}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) & \Delta \boldsymbol{H}^{\ominus}=+483.7 \mathrm{~kJ} \mathrm{~mol}^{-1}
\end{array}
$$

### 2.2.3 Enthalpy diagrams

Consider the following reaction.

$$
\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}(\mathrm{~s})+12 \mathrm{O}_{2}(\mathrm{~g}) \rightarrow 12 \mathrm{CO}_{2}(\mathrm{~g})+11 \mathrm{H}_{2} \mathrm{O}(l) \quad \Delta \boldsymbol{H}^{\ominus}=\mathbf{- 5 6 5 0} \mathbf{k J ~ m o l}^{-1}
$$

The negative sign of $\Delta H^{\theta}$ in the above equation means that the enthalpy of the products is lower than that of the reactants. This decrease in enthalpy appears as heat evolved to the surroundings. The combustion of sucrose is an exothermic reaction.

$$
\mathrm{N}_{2}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \rightarrow 2 \mathrm{NO}(\mathrm{~g}) \quad \Delta \boldsymbol{H}^{\theta}=\mathbf{1 8 0 . 5 0} \mathrm{kJ} \mathrm{~mol}^{-1}
$$

In the above reaction the products have a higher enthalpy than the reactants so $\Delta H^{\ominus}$ is positive. To produce this increase in enthalpy, heat is absorbed from the surroundings. The reaction is endothermic. An enthalpy diagram is a diagrammatic representation of enthalpy changes in a process. Figure 2.3 below shows how exothermic and endothermic reactions can be represented through such diagrams as are already shown in the Table 2.1).

Figure 2.3 Enthalpy diagrams of (a) endothermic and (b) exothermic processes

### 2.2.4 Enthalpy changes and standard enthalpy changes

- Standard enthalpy change of formation, $\Delta \boldsymbol{H}_{f}^{\ominus}$

The standard enthalpy of formation, $\Delta H_{f}^{\theta}$ of a substance is the enthalpy change that occurs in the formation of one mole of the substance in the standard state from the reference forms of the elements in their standard states. The reference forms of the elements in all but a few cases are the most stable forms of the elements at one atm ( 101325 Pa ) and the given temperature. The $\theta$ symbol denotes that the enthalpy change is a standard enthalpy change, and the subscript " $f$ " signifies that the reaction is one in which a substance is formed from its elements. Because the formation of the most stable form of an element from itself is no change at all that is the standard enthalpy of a pure element in its reference form is 0 .

For example, listed below are the most stable forms of some elements/ compounds at 298.15 K , the temperature at which thermochemical data are commonly tabulated.

$$
\mathrm{Na}(\mathrm{~s}), \mathrm{H}_{2}(\mathrm{~g}), \mathrm{N}_{2}(\mathrm{~g}), \mathrm{O}_{2}(\mathrm{~g}), \mathrm{C}\left(\mathrm{~s}, \text { graphite), } \mathrm{Br}_{2}(\mathrm{l})\right.
$$

## Example :

One may concern the situation with carbon. In addition to graphite, carbon also exists naturally in the form of diamond. However, because there is a measurable enthalpy difference between them, they cannot both be assigned $\Delta H_{f}^{\theta}=0$

$$
\mathrm{C}(\mathrm{~s}, \text { graphite }) \rightarrow \mathrm{C}(\mathrm{~s}, \text { diamond }) ; \Delta H_{f}^{\ominus}=1.9 \mathrm{~kJ} \mathrm{~mol}^{-1} .
$$

We choose as the reference form the more stable form, the one with the lower enthalpy. Thus, we assign $\Delta H_{f(\text { graphite })}^{\circ}=0$.

The physical state of the product of the formation reaction must be indicated explicitly if it is not the most stable one at $25^{\circ} \mathrm{C}$ and 1 atm pressure

$$
\begin{aligned}
& \mathrm{H}_{2}(\mathrm{~g})+{ }_{2}^{1} \mathrm{O}_{2}(\mathrm{~g}) \rightarrow \mathrm{H}_{2} \mathrm{O}_{(\mathrm{l})} \\
& \Delta H_{f}^{\ominus}=-285.8 \mathrm{~kJ} \mathrm{~mol}^{-1} \\
& \mathrm{H}_{2}(\mathrm{~g})+\frac{1}{2} \mathrm{O}_{2}(\mathrm{~g}) \rightarrow \mathrm{H}_{2} \mathrm{O}(\mathrm{~g}) \\
& \Delta H_{f}^{\theta}=-241.8 \mathrm{~kJ} \mathrm{~mol}^{-1}
\end{aligned}
$$

Note that the difference between these two $\Delta \boldsymbol{H}_{f}^{\ominus}$ values is just the heat of vapourization $\left(44 \mathrm{~kJ} \mathrm{~mol}^{-1}\right)$ of water.

We often use standard enthalpies of formation in a variety of calculations and the first thing we must do is to write the chemical equation to which a $\Delta H_{f}^{\theta}$ value applies, as illustrated in following examples in the text.

The standard enthalpy of formation of formaldehyde (HCHO) is $-108 \mathrm{~kJ} \mathrm{~mol}^{-1}$ at 298 K and the chemical equation below shows this event.

$$
\mathrm{H}_{2}(\mathrm{~g})+\frac{1}{2} \mathrm{O}_{2}(\mathrm{~g})+\mathrm{C}(\text { graphite }) \rightarrow \mathrm{HCHO}(\mathrm{~g}) \quad \Delta \boldsymbol{H}_{f}^{\ominus}=-\mathbf{1 0 8} \mathbf{~ k J ~ m o l}^{\mathbf{- 1}}
$$

Before going to discuss some examples it is worth defining standard enthalpies of some chemical reactions/events.

- Standard enthalpy change of combustion, $\Delta \boldsymbol{H}_{\boldsymbol{c}}^{\ominus}$

It is the enthalpy change when one mole of an element or a compound in the standard state undergoes complete combustion with excess oxygen (or one may say air) in the standard state to give the products in the standard state.

$$
\begin{array}{ll}
\mathrm{C}_{3} \mathrm{H}_{8}(\mathrm{~g})+5 \mathrm{O}_{2}(\mathrm{~g}) \rightarrow 3 \mathrm{CO}_{2}(\mathrm{~g})+4 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) & \Delta \boldsymbol{H}_{c\left[\mathrm{C}_{3} H_{8}(\mathrm{~g})\right]}=\mathbf{- 2 2 1 9 . 9} \mathbf{~ k J ~ m o l}^{\mathbf{- 1}} \\
\mathrm{C}(\mathrm{~s})+\mathrm{O}_{2}(\mathrm{~g}) \rightarrow \mathrm{CO}_{2}(\mathrm{~g}) & \Delta \boldsymbol{H}_{c[\mathrm{~g}(\mathrm{~s})]}^{\ominus}=-\mathbf{3 9 3 . 5} \mathbf{k J ~ m o l}^{-1}
\end{array}
$$

## G.C.E. (A/L) CHEMISTRY : UNIT 5 Energetics

- Standard enthalpy change of bond dissociation, $\Delta \boldsymbol{H}_{\boldsymbol{D}}^{\circ}$

It is the enthalpy change when a gaseous compound in the standard state undergoes dissociation to gaseous atoms or components in the standard state by breaking a mole of bonds.

$$
\begin{array}{ll}
\mathrm{H}_{2}(\mathrm{~g}) \rightarrow 2 \mathrm{H}(\mathrm{~g}) & \Delta \boldsymbol{H}_{\boldsymbol{D}}^{\ominus}=\mathbf{4 3 2} \mathbf{k J ~ m o l}^{\mathbf{- 1}} \\
\mathrm{CH}_{4}(\mathrm{~g}) \rightarrow \mathrm{CH}_{3}(\mathrm{~g})+\mathrm{H}(\mathrm{~g}) & \Delta \boldsymbol{H}_{\boldsymbol{D}}^{\ominus}=\mathbf{4 2 8} \mathbf{k J ~ m o l}^{-\mathbf{1}} \\
\mathrm{CH}_{3}(\mathrm{~g}) \rightarrow \mathrm{CH}_{2}(\mathrm{~g})+\mathrm{H}(\mathrm{~g}) & \Delta \boldsymbol{H}_{\boldsymbol{D}}^{\ominus}=\mathbf{4 4 1} \mathbf{k J ~ m o l}^{-\mathbf{1}} \\
\mathrm{CH}_{2}(\mathrm{~g}) \rightarrow \mathrm{CH}(\mathrm{~g})+\mathrm{H}(\mathrm{~g}) & \Delta \boldsymbol{H}_{\boldsymbol{D}}^{\ominus}=\mathbf{4 5 4} \mathbf{k J ~ m o l}^{\mathbf{- 1}} \\
\mathrm{CH}(\mathrm{~g}) \rightarrow \mathrm{C}(\mathrm{~g})+\mathrm{H}(\mathrm{~g}) & \Delta \boldsymbol{H}_{\boldsymbol{D}}^{\ominus}=\mathbf{3 4 4} \mathbf{k J ~ m o l}^{\mathbf{- 1}}
\end{array}
$$

Therefore the bond dissociation energy change of methane is the mean value of the above four enthalpy values.
Mean standard enthalpy change of $=\frac{(428+441+454+344) \mathrm{kJ} \mathrm{mol}^{-1}}{4}$ bond dissociation of $\mathrm{CH}_{4}(\mathrm{~g})$

$$
=416.75 \mathrm{~kJ} \mathrm{~mol}^{-1}
$$

- Standard enthalpy change of neutralization, $\Delta \boldsymbol{H}_{\text {neu }}^{\ominus}$

It is the enthalpy change when a mole of an aqueous $\mathrm{H}^{+}$ions and a mole of an aqueous $\mathrm{OH}^{-}$ions in the standard state react to form a mole of liquid water.

$$
\mathrm{H}^{+}(\mathrm{aq})+\mathrm{OH}^{-}(\mathrm{aq}) \rightarrow \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \quad \Delta \boldsymbol{H}_{\text {neu }}^{\ominus}=\mathbf{- 5 7} \mathbf{~ k J ~ m o l}^{\mathbf{- 1}}
$$

- Standard enthalpy change of solvation, $\Delta \boldsymbol{H}_{\text {sol }}^{\ominus}$

It is the enthalpy change when a mole of gaseous ions in the standard state changes into a solution to form $1.0 \mathrm{~mol} \mathrm{dm}^{-3}$.

$$
\mathrm{M}^{\mathrm{n+}}(\mathrm{~g})+\text { solvent } \rightarrow \mathrm{M}^{\mathrm{n+}}(\text { solvent })
$$

- Standard enthalpy change of hydration, $\Delta \boldsymbol{H}_{\text {hyd }}^{\ominus}$

It is the enthalpy change when a mole of gaseous ions in the standard state changes into a solution with water with the concentration of $1.0 \mathrm{~mol} \mathrm{dm}^{-3}$.

$$
\mathrm{Na}^{+}(\mathrm{g})+\text { water } \rightarrow \mathrm{Na}^{+}(\mathrm{aq}) \quad \Delta \boldsymbol{H}_{\boldsymbol{h} \boldsymbol{y} \boldsymbol{d}}^{\ominus}=-406 \mathbf{~ k J ~ m o l}^{-1}
$$

- Standard enthalpy change of dissolution, $\Delta \boldsymbol{H}_{\text {dissolution }}^{\ominus}$

It is the enthalpy change when a mole of a substance in the standard state dissolved in a solvent to form a solution with the concentration of $1.0 \mathrm{~mol} \mathrm{dm}^{-3}$ (a saturated solution formed by a sparingly soluble salt).

$$
\mathrm{NaCl}(\mathrm{~s})+\text { water } \rightarrow \mathrm{NaCl}(\mathrm{aq}) \quad \Delta \boldsymbol{H}_{\text {dissolution }}^{\ominus}=\mathbf{1} \mathbf{~ k J ~ m o l}^{-1}
$$

- Standard enthalpy change of sublimation, $\Delta \boldsymbol{H}_{\text {sub }}^{\ominus}$

It is the enthalpy change when a mole of a solid element or a mole of a solid compound in the standard state converts completely into a gas at its standard state.

$$
\mathrm{Ca}(\mathrm{~s}) \rightarrow \mathrm{Ca}(\mathrm{~g}) \quad \Delta \boldsymbol{H}_{\text {sub }}^{\ominus}=\mathbf{1 9 3} \mathbf{~ k J ~ m o l}^{-1}
$$

- Standard enthalpy change of evaporization, $\Delta H_{\text {evap }}^{\ominus}$

It is the enthalpy change when a mole of a liquid compound or an element in the standard state converts into a mole of gaseous compound or element at its standard state.

$$
\mathrm{Br}_{2}(\mathrm{l}) \rightarrow \mathrm{Br}_{2}(\mathrm{~g}) \quad \Delta \boldsymbol{H}_{\text {evap }}^{\ominus}=30.91 \mathbf{~ k J ~ m o l}^{-1}
$$

- Standard enthalpy change of fusion, $\Delta \boldsymbol{H}_{f}^{\ominus}$ us

It is the enthalpy change when a mole of a solid compound or an element in the standard state converts into a mole of liquid compound or element at its standard state.

$$
\mathrm{Al}(\mathrm{~s}) \rightarrow \mathrm{Al}(\mathrm{l}) \quad \Delta \boldsymbol{H}_{f u s}^{\ominus}=\mathbf{1 0 . 7} \mathbf{~ k J ~ m o l}^{-1}
$$

- Standard enthalpy change of atomization, $\Delta \boldsymbol{H}_{a t}^{\ominus}$

It is the enthalpy change when an element in the standard state converts into a one mole of gaseous atoms at the standard state.

$$
1 / 2 \mathrm{Cl}_{2}(\mathrm{~g}) \rightarrow \mathrm{Cl}(\mathrm{~g}) \quad \Delta H_{a t}^{\ominus}=121 \mathrm{~kJ} \mathrm{~mol}^{-1}
$$

- Standard enthalpy change of first ionization, $\Delta H_{I E 1}^{\ominus}$

It is the enthalpy change when a mole of a gaseous mono-positive ions at standard state are formed by removing an electron from each atom that is most weakly bonded to the nucleus from a mole of gaseous atoms of an element in standard state.

$$
\mathrm{Na}(\mathrm{~g}) \rightarrow \mathrm{Na}^{+}(\mathrm{g})+\mathrm{e}
$$

$$
\Delta H_{I E 1}^{\ominus}=496 \mathrm{~kJ} \mathrm{~mol}^{-1}
$$

- Standard enthalpy change of electron gain, $\Delta \boldsymbol{H}_{E G}^{\ominus}$

It is the enthalpy change when a mole of gaseous mono-negative ions are formed by gaining electrons to a mole of gaseous atom at the standard state.

$$
\mathrm{Cl}(\mathrm{~g})+\mathrm{e} \rightarrow \mathrm{Cl}^{-}(\mathrm{g}) \quad \Delta \boldsymbol{H}_{E G}^{\ominus}=\mathbf{- 3 4 9} \mathbf{~ k J ~ m o l}^{-1}
$$

- Standard lattice dissociation enthalpy change of an ionic compound, $\Delta \boldsymbol{H}_{L}^{\ominus}$

It is the enthalpy change when one mole of a solid ionic compound is converted to its gaseous positive and negative ions at the standard state.

$$
\mathrm{NaCl}(\mathrm{~s}) \rightarrow \mathrm{Na}^{+}(\mathrm{g})+\mathrm{Cl}^{-}(\mathrm{g}) \quad \Delta \boldsymbol{H}_{L}^{\ominus}=+\mathbf{7 8 8} \mathbf{~ k J ~ m o l}^{-1}
$$

## G.C.E. (A/L) CHEMISTRY : UNIT 5 Energetics

### 2.2.5 Indirect determination of $\Delta \boldsymbol{H}\left(\Delta \boldsymbol{H}^{\theta}\right)$ : Hess Law

One of the reasons that the enthalpy concept is so useful is that a large number of heat of reaction can be calculated from a small number of measurements. The following features of enthalpy change make this possible.
$\Delta H$ is an extensive property and is also a function of state. Consider the standard enthalpy change of formation of $\mathrm{NO}(\mathrm{g})$ from its elements at $25^{\circ} \mathrm{C}$.

$$
\mathrm{N}_{2}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \rightarrow 2 \mathrm{NO}(\mathrm{~g}) \quad \Delta \boldsymbol{H}^{\theta}=\mathbf{1 8 0 . 5 0} \mathbf{~ k J ~ m o l}^{-1}
$$

To express the enthalpy change in terms of one mole of $\mathrm{NO}(\mathrm{g})$ we divide all coefficients and the value $\Delta H^{\theta}$ by two.

$$
\frac{1}{2} \mathrm{~N}_{2}(\mathrm{~g})+\frac{1}{2} \mathrm{O}_{2}(\mathrm{~g}) \rightarrow \mathrm{NO}(\mathrm{~g}) \quad \Delta \boldsymbol{H}^{\theta}=\mathbf{9 0 . 2 5} \mathbf{~ k J ~ m o l}^{-\mathbf{1}}
$$

$\Delta H^{\theta}$ changes sign when a process is reversed as the change in a function of state reverses sign. Thus, for the decomposition of one mole of $\mathrm{NO}(\mathrm{g})$, standard enthalpy change is $\mathbf{- 9 0 . 2 5} \mathbf{~ k J ~ m o l}^{\mathbf{- 1}}$ which is the negative value of the enthalpy for the formation of one mole of $\mathrm{NO}(\mathrm{g})$.

$$
\mathrm{NO}(\mathrm{~g}) \rightarrow \frac{1}{2} \mathrm{~N}_{2}(\mathrm{~g})+\frac{1}{2} \mathrm{O}_{2}(\mathrm{~g}) \quad \Delta \boldsymbol{H}^{\theta}=\mathbf{- 9 0 . 2 5} \mathrm{kJ} \mathrm{~mol}^{\boldsymbol{- 1}}
$$

## An example for Hess Law of constant heat summation:

The standard enthalpy change for the formation of $\mathrm{NO}_{2}(\mathrm{~g})$ from $\mathrm{N}_{2}(\mathrm{~g})$ and $\mathrm{O}_{2}(\mathrm{~g})$ can be found as follows.

$$
\frac{1}{2} \mathrm{~N}_{2}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \rightarrow \mathrm{NO}_{2}(\mathrm{~g}) \quad \Delta H^{\theta}=?
$$

We can think of the reaction as proceeding in two steps: First we form $\mathrm{NO}(\mathrm{g})$ from $\mathrm{N}_{2}(\mathrm{~g})$ and $\mathrm{O}_{2}(\mathrm{~g})$, and then $\mathrm{NO}_{2}(\mathrm{~g})$ from $\mathrm{NO}(\mathrm{g})$ and $\mathrm{O}_{2}(\mathrm{~g})$. When the thermochemical equations for these two steps are added together with their individual and distinctive $\Delta H^{\theta}$ values, we get the overall equation and $\Delta H^{\theta}$ value that we are seeking.

$$
\begin{array}{ll}
\frac{1}{2} \mathrm{~N}_{2}(\mathrm{~g})+\frac{1}{2} \mathrm{O}_{2}(\mathrm{~g}) \rightarrow \mathrm{NO}(\mathrm{~g}) & \Delta H^{\theta}=90.25 \mathrm{~kJ} \mathrm{~mol}^{-1} \\
\mathrm{NO}(\mathrm{~g})+\frac{1}{2} \mathrm{O}_{2}(\mathrm{~g}) \rightarrow \mathrm{NO}_{2}(\mathrm{~g}) & \Delta H^{\theta}=-57.07 \mathrm{~kJ} \mathrm{~mol}^{-1} \\
\frac{1}{\mathbf{1}} \mathbf{N}_{\mathbf{2}}(\mathrm{g})+\mathbf{O}_{\mathbf{2}}(\mathrm{g}) \rightarrow \mathbf{N O}_{\mathbf{2}}(\mathrm{g}) & \Delta \boldsymbol{H}^{\theta}=+\mathbf{3 3 . 1 8} \mathrm{kJ} \mathrm{~mol}^{-1}
\end{array}
$$

As of the above example the Hess law states the principle we used: i.e.
If a process occurs in stages or steps (even if only hypothetically), the enthalpy change for the overall process is the sum of the enthalpy changes for the individual steps.

## G.C.E. (A/L) CHEMISTRY : UNIT 5 Energetics

In other words, Hess law is simply a consequence of the state function property of enthalpy. Regardless of the path taken in going from the initial state to the final state, $\Delta H$ (or $\Delta H^{\theta}$ if the process is carried out under standard states) has the same value or it is independent of the route.

This concept can also be illustrated by an enthalpy diagram and a thermochemical cycle as described in Figure 2.4 and 2.5 respectively.

(a)

(b)

Figure 2.4 Enthalpy changes for an exothermic reaction using two different ways of getting from reactants $A$ to products $B$. (a) direct conversion and (b) two-step process involving some intermediates

Figure 2.4 describes the statement of Hess Law, that is, if you convert reactants A into products B, the overall enthalpy change will be exactly the same whether you do it in one step or two steps or many steps. In either case, the overall enthalpy change must be the same, because it is governed by the relative positions of the reactants and products on the enthalpy diagram.

Calculations can also be done by setting them out as enthalpy diagrams as above, but there is a much simpler way of doing it which needs a cycle to understand the process as below where the conversion of reactant A to product B is considered in two routes.

Figure 2.5 Thermochemical cycle
When we write the thermochemical cycle it is important to follow the instructions given below.

First write the chemical reaction in which the enthalpy change needs to find and write $\Delta H$ over the top of the arrow. Then include the other reactions with thermodynamic information to the same diagram to make a thermochemical cycle (Hess law cycle), and write the known enthalpy changes over the arrows for each of the other reactions. Find two routes around the diagram, always going with the flow of the various arrows. There must be no arrows going in the opposite direction.

In addition, it is necessary to multiply the known enthalpy values by a number of moles involved in a particular reaction. For example, standard enthalpy changes of combustion starts with one mole of the substance (carbon) burning and the enthalpy value should be multiplied by the number of carbon atoms involved in the reaction (see the example given below). Remember that this should also be included when the problem is solved with the equations.

## Example:

Suppose we want the standard enthalpy change for the following reaction.

$$
3 \mathrm{C}(\mathrm{~s})+4 \mathrm{H}_{2}(\mathrm{~g}) \rightarrow \mathrm{C}_{3} \mathrm{H}_{8}(\mathrm{~g}) \quad \Delta H^{\ominus}=?
$$

Now we have a question that how should we proceed? If we try to get graphite and hydrogen to react, but it will not go to completion. Furthermore, the product will not be limited to propane and several other hydrocarbons will form as well. The fact is that we cannot directly measure $\Delta H^{\theta}$ for reaction above. Instead, we must resort to an indirect calculation from $\Delta H^{\theta}$ values that can be established by experiment. Here is where Hess law is of greatest value. It permits us to calculate $\Delta H^{\theta}$ values that we cannot measure directly.

To determine an enthalpy change with Hess law, we need to combine the appropriate chemical equations. A good starting point is to write chemical equations for the given combustion reactions based on one mole of the indicated reactant. Considering that the products of the combustion of carbon-hydrogen-oxygen compounds are $\mathrm{CO}_{2}(\mathrm{~g})$ and $\mathrm{H}_{2} \mathrm{O}(\mathrm{l})$ we can find the path to solve the problem as follows.

$$
\begin{array}{ll}
\mathrm{C}_{3} \mathrm{H}_{8}(\mathrm{~g})+5 \mathrm{O}_{2}(\mathrm{~g}) \rightarrow 3 \mathrm{CO}_{2}(\mathrm{~g})+4 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) & \Delta H^{\theta}=-2219.9 \mathrm{~kJ} \mathrm{~mol}^{-1} \\
\mathrm{C}(\mathrm{~s})+\mathrm{O}_{2}(\mathrm{~g}) \rightarrow \mathrm{CO}_{2}(\mathrm{~g}) & \Delta H^{\theta}=-393.5 \mathrm{~kJ} \mathrm{~mol}^{-1} \\
\frac{1}{2} \mathrm{O}_{2}(\mathrm{~g})+\mathrm{H}_{2}(\mathrm{~g}) \rightarrow \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) & \Delta H^{\theta}=-285.8 \mathrm{~kJ} \mathrm{~mol}^{-1}
\end{array}
$$

Reverse of the reaction (a).

$$
\begin{equation*}
3 \mathrm{CO}_{2}(\mathrm{~g})+4 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightarrow \mathrm{C}_{3} \mathrm{H}_{8}(\mathrm{~g})+5 \mathrm{O}_{2}(\mathrm{~g}) \quad \Delta H^{\theta}=2219.9 \mathrm{~kJ} \mathrm{~mol}^{-1} \tag{a}
\end{equation*}
$$

Considering the reactants of the reaction of interest, $\mathrm{C}(\mathrm{s})$ and $\mathrm{H}_{2}(\mathrm{~g})$, to get the proper number of moles of each, we must multiply equation (b) by three and equation (c) by four.

$$
\begin{array}{ll}
3 \mathrm{C}(\mathrm{~s})+3 \mathrm{O}_{2}(\mathrm{~g}) \rightarrow 3 \mathrm{CO}_{2}(\mathrm{~g}) & \Delta H^{\theta}=3\left(-393.5 \mathrm{~kJ} \mathrm{~mol}^{-1}\right)=-1180.5 \mathrm{~kJ} \mathrm{~mol}^{-1} \quad(\mathrm{~b})^{\prime} \\
2 \mathrm{O}_{2}(\mathrm{~g})+4 \mathrm{H}_{2}(\mathrm{~g}) \rightarrow 4 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) & \Delta H^{\theta}=4\left(-285.8 \mathrm{~kJ} \mathrm{~mol}^{-1}\right)=-1143.2 \mathrm{~kJ} \mathrm{~mol}^{-1} \quad(\mathrm{c})^{\prime} \tag{c}
\end{array}
$$

Here is the overall change we have described: 3 mol of $\mathrm{C}(\mathrm{s})$ and $4 \mathrm{~mol}^{\text {of }} \mathrm{H}_{2}(\mathrm{~g})$ have been consumed, and 1 mol of $\mathrm{C}_{3} \mathrm{H}_{8}(\mathrm{~g})$ has been produced. This is exactly what is required. We can now combine the three modified equations by summing them up (i.e. $\left.(\mathrm{a})^{\prime}+(\mathrm{b})^{\prime}+(\mathrm{c})^{\prime}\right)$

$$
\begin{array}{ll}
3 \mathrm{CO}_{2}(\mathrm{~g})+4 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightarrow \mathrm{C}_{3} \mathrm{H}_{8}(\mathrm{~g})+5 \mathrm{O}_{2}(\mathrm{~g}) \quad \Delta H^{\theta}=2219.9 \mathrm{~kJ} \mathrm{~mol}^{-1} & \text { (a) } \\
3 \mathrm{C}(\mathrm{~s})+3 \mathrm{O}_{2}(\mathrm{~g}) \rightarrow 3 \mathrm{CO}_{2}(\mathrm{~g}) & \Delta H^{\theta}=3\left(-393.5 \mathrm{~kJ} \mathrm{~mol}^{-1}\right)=-1180.5 \mathrm{~kJ} \mathrm{~mol}^{-1} \\
2 \mathrm{O}_{2}(\mathrm{~g})+4 \mathrm{H}_{2}(\mathrm{~g}) \rightarrow 4 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) & \Delta H^{\theta}=4\left(-285.8 \mathrm{~kJ} \mathrm{~mol}^{-1}\right)=-1143.2 \mathrm{~kJ} \mathrm{~mol}^{-1}
\end{array}
$$

$$
3 \mathrm{C}(\mathrm{~s})+4 \mathrm{H}_{2}(\mathrm{~g}) \rightarrow \mathrm{C}_{3} \mathrm{H}_{8}(\mathrm{~g}) \Delta H^{\theta}=-103.8 \mathrm{~kJ} \mathrm{~mol}^{-1}
$$

Solving the above with a thermochemical cycle:

$$
\Delta H=3\left(-393.5 \mathrm{~kJ} \mathrm{~mol}^{-1}\right)+4\left(-285.8 \mathrm{~kJ} \mathrm{~mol}^{-1}\right)+2219.9 \mathrm{~kJ} \mathrm{~mol}^{-1}=\mathbf{- 1 0 3 . 8} \mathbf{~ k J ~ m o l}{ }^{\mathbf{1}}
$$

## Representation and solving of the above with an enthalpy diagram:

In the enthalpy diagrams we have drawn, we have not written any numerical values on the enthalpy axis. This is because we cannot determine absolute values of enthalpy, $H$. However, enthalpy is a function of state, so changes in enthalpy, $\Delta H$ have unique values. We can deal just with these changes. Nevertheless, as with many other properties, it is still useful to have a starting point, a zero value.

Figure 2.6 Enthalpy diagram for $3 \mathrm{C}(\mathrm{s})+4 \mathrm{H}_{2}(\mathrm{~g}) \rightarrow \mathrm{C}_{3} \mathrm{H}_{8}(\mathrm{~g})$ reaction. (a) represents each process with the enthalpy values with respect to the direction of reaction. (b) shows the enthalpy-gap and we can decide the sign according to the direction of the reactions wanted.

## Standard enthalpies of reaction

We have learned that if the reactants and products of a reaction are in their standard states, the enthalpy change is the standard enthalpy change, which we can denote as $\Delta H^{\theta}$ or $\Delta H_{r x n}^{\ominus}$. One of the primary uses of standard enthalpies of formation is in calculating standard enthalpies of reaction.

## Example 2.1

Calculate the standard enthalpy of reaction for the decomposition of sodium bicarbonate, a side reaction that occurs when baking soda is used in baking by using Hess law.

$$
2 \mathrm{NaHCO}_{3}(\mathrm{~s}) \rightarrow \quad \mathrm{Na}_{2} \mathrm{CO}_{3}(\mathrm{~s})+\mathrm{H}_{2} \mathrm{O}(l)+\mathrm{CO}_{2}(\mathrm{~g}) \quad \Delta H_{r x n}^{\ominus}=?
$$

## Answer:

From Hess law, we see that the following four equations yield the above equation when added together.

$$
\begin{array}{ll}
2 \mathrm{NaHCO}_{3}(\mathrm{~s}) \rightarrow 2 \mathrm{Na}(\mathrm{~s})+\mathrm{H}_{2}(\mathrm{~g})+2 \mathrm{C}(\text { graphite })+3 \mathrm{O}_{2}(\mathrm{~g}) & \Delta H^{\theta}=-2 \Delta H_{f\left[\mathrm{NaHCO}_{3}(\mathrm{~s})\right]}^{\ominus} \\
2 \mathrm{Na}(\mathrm{~s})+\mathrm{C}(\text { graphite })+{ }_{2}^{3} \mathrm{O}_{2}(\mathrm{~g}) \rightarrow \mathrm{Na}_{2} \mathrm{CO}_{3}(\mathrm{~s}) & \Delta H^{\theta}=\Delta H_{f\left[\mathrm{Na} a_{2} \mathrm{CO}_{3}(\mathrm{~s})\right]} \\
\frac{1}{2} \mathrm{O}_{2}(\mathrm{~g})+\mathrm{H}_{2}(\mathrm{~g}) \rightarrow \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) & \Delta H^{\theta}=\Delta H_{f\left[H_{2} \mathrm{O}(\mathrm{l})\right]} \\
\mathrm{C}(\text { graphite })+\mathrm{O}_{2}(\mathrm{~g}) \rightarrow \mathrm{CO}_{2}(\mathrm{~g}) & \Delta H^{\theta}=\Delta H_{f\left[\left[\mathrm{co}_{2}(\mathrm{~g})\right]\right.} \tag{d}
\end{array}
$$

$$
2 \mathrm{NaHCO}_{3}(\mathrm{~s}) \rightarrow \mathrm{Na}_{2} \mathrm{CO}_{3}(\mathrm{~s})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})+\mathrm{CO}_{2}(\mathrm{~g}) \quad \Delta \boldsymbol{H}_{r x n}^{\ominus}=?
$$

Equation (a) is the reverse of the equation representing the formation of two moles of $\mathrm{NaHCO}_{3}(\mathrm{~s})$ from its elements. This means that $\Delta H^{\theta}$ for reaction (a) is the negative of twice $\left.\Delta H_{f[\mathrm{NaHCO}}^{3} \mathrm{~s}(\mathrm{~s})\right]$. Equations (b), (c) and (d) represent the formation of one mole each of $\mathrm{Na}_{2} \mathrm{CO}_{3}(\mathrm{~s}), \mathrm{H}_{2} \mathrm{O}(\mathrm{l})$ and $\mathrm{CO}_{2}(\mathrm{~g})$. Thus, we can express the value of $\Delta H^{\ominus}$ for the reaction;

$$
\begin{aligned}
& \Delta H_{r x n}^{\ominus}=\Delta H_{f\left[\mathrm{Na}_{2} \mathrm{CO}_{3}(\mathrm{~s})\right]}^{\ominus}+\Delta H_{f\left[\mathrm{H}_{2} \mathrm{O}(\mathrm{l})\right]}^{\ominus}+\Delta H_{f\left[\mathrm{CO}_{2}(\mathrm{~g})\right]}^{\ominus}+\left(-2 \Delta H_{f\left[\mathrm{NaHCO}_{3}(\mathrm{~s})\right]}^{\ominus}\right) \\
= & \left(-1130.68 \mathrm{~kJ} \mathrm{~mol}^{-1}\right)+\left(-187.78 \mathrm{~kJ} \mathrm{~mol}^{-1}\right)+\left(-393.51 \mathrm{~kJ} \mathrm{~mol}^{-1}\right)+\left(1901.62 \mathrm{~kJ} \mathrm{~mol}^{-1}\right) \\
= & \mathbf{1 8 9 . 6 5} \mathbf{~ k J ~ m o l}^{-1}\left(\text { For } \mathbf{2} \text { moles of } \mathrm{NaHCO}_{3(\mathrm{~s})}\right) \\
= & \mathbf{9 4 . 8 2 5} \mathbf{~ k J ~ m o l}^{-1}\left(\text { For } \mathbf{1} \text { mole of } \mathrm{NaHCO}_{3}(\mathrm{~s})\right)
\end{aligned}
$$

We can use the enthalpy diagram to visualize the Hess law procedure and to show how the state function property of enthalpy enables us to arrive at the equation above.

Imagine the decomposition of sodium bicarbonate taking place in two steps. In the first step, suppose a vessel contains 2 mol of $\mathrm{NaHCO}_{3(\mathrm{~s})}$ which is allowed to decompose into $2 \mathrm{~mol} \mathrm{Na}(\mathrm{s}), 2 \mathrm{~mol} \mathrm{C}$ (graphite), and 3 mol of $\mathrm{O}_{2}(\mathrm{~g})$ as in equation (a) above. In the second step, recombine $2 \mathrm{~mol} \mathrm{Na}(\mathrm{s}), 2 \mathrm{~mol} \mathrm{C}$ (graphite), 1 mol of $\mathrm{H}_{2}(\mathrm{~g})$ and 3 mol of $\mathrm{O}_{2}(\mathrm{~g})$ to form the products according to equations (b), (c) and (d) above.

Step 1: $2 \times\left[\mathrm{NaHCO}_{3}(\mathrm{~s}) \rightarrow \mathrm{Na}(\mathrm{s})+1 / 2 \mathrm{H}_{2}(\mathrm{~g})+\mathrm{C}\right.$ (graphite) $\left.+3 / 2 \mathrm{O}_{2}(\mathrm{~g})\right]$

$$
\Delta \boldsymbol{H}^{\theta}=2 \times\left(-\Delta H_{f}^{\theta}\left[\mathrm{NaHCO}_{3}(\mathrm{~s})\right]\right)=(2 \mathrm{~mol})\left[-\left(-950.81 \mathrm{~kJ} \mathrm{~mol}^{-1}\right)\right]
$$

Step 2: 2 Na (s) +C (graphite) $+3 / 2 \mathrm{O}_{2}(\mathrm{~g}) \rightarrow \mathrm{Na}_{2} \mathrm{CO}_{3}(\mathrm{~s})$

$$
\begin{aligned}
& \left.\Delta H^{\theta}=\Delta H_{f}^{\theta}\left[\mathrm{Na}_{2} \mathrm{CO}_{3}(\mathrm{~s})\right]=\left(\mathbf{1} \mathbf{~ m o l ~ N a}_{2} \mathrm{CO}_{3}\right)\left(-\mathbf{1 1 3 0 . 6 8} \mathrm{kJ} \mathrm{~mol}^{-1}\right)\right] \\
& \mathrm{C} \text { (graphite) }+\mathrm{O}_{2}(\mathrm{~g}) \rightarrow \mathrm{CO}_{2}(\mathrm{~g}) \\
& \left.\Delta \boldsymbol{H}^{\theta}=\Delta H_{f}^{\theta}\left[\mathbf{C O}_{2}(\mathrm{~g})\right]=\left(\mathbf{1} \mathrm{mol} \mathrm{CO}_{2}\right)\left(-393.51 \mathrm{~kJ} \mathrm{~mol}^{-1}\right)\right] \\
& \mathrm{H}_{2}(\mathrm{~g})+1 / 2 \mathrm{O}_{2}(\mathrm{~g}) \rightarrow \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \\
& \left.\Delta \boldsymbol{H}^{\theta}=\Delta H_{f}^{\theta}\left[\mathrm{H}_{\mathbf{2}} \mathrm{O}(\mathbf{I})\right]=\left(\mathbf{1} \mathrm{mol} \mathrm{H}_{\mathbf{2}} \mathbf{O}\right)\left(-\mathbf{1 8 7 . 7 8} \mathrm{kJ} \mathrm{~mol}^{-1}\right)\right]
\end{aligned}
$$

Because enthalpy is a state function and the change of any state function is independent of the path chosen, the enthalpy change for the overall reaction is the sum of the standard enthalpy changes of the individual steps as shown in the above equation according to Hess law. Therefore, the above procedure is a specific application of the following more general relationship for a standard enthalpy of reaction.

$$
\Delta H_{r x n}^{\ominus}=\sum v_{p} H_{f[\text { products }]}^{\ominus}-\sum v_{r} H_{f[\text { reactants }]}^{\ominus}
$$

## G.C.E. (A/L) CHEMISTRY : UNIT 5 Energetics

where $v_{p}$ and $v_{r}$ are the stoichiometric coefficients of products and reactants, respectively. The enthalpy change of the reaction $\left(\Delta H_{r \times n}^{\ominus}\right)$ (sometimes written as $\Delta H_{r}^{\ominus}$ ) is the sum of terms for the products minus the sum of terms for the reactants.

Simply for example, consider the hypothetical reaction

$$
a A+b B \rightarrow c C+d D \quad \Delta H_{r x n}^{\ominus}=?
$$

where $a, b, c$ and $d$ are stoichiometric coefficients. For this reaction $\Delta H_{r x n}^{\circ}$ is given by

$$
\Delta H_{r x n}^{\ominus}=\left[c \Delta H_{f[\mathrm{C}]}^{\ominus}+d \Delta H_{f[\mathrm{D}]}^{\ominus}\right]-\left[a \Delta H_{f[\mathrm{~A}]}^{\ominus}+b \Delta H_{f[\mathrm{~B}]}^{\ominus}\right]
$$

In order to use the above equation to calculate $\Delta H_{r x n}^{\ominus}$, we must know the $\Delta H_{f}^{\theta}$ values of the compounds that take part in the reaction. To determine these values we can apply the direct method or the indirect method.

## The Direct Method;

This method of measuring $\Delta H_{f}^{\theta}$ works for compounds that can be readily synthesized from their elements. Suppose we want to know the enthalpy, $\Delta H_{r x n}^{\ominus}$ for the combustion of $\mathrm{C}_{2} \mathrm{H}_{6}(\mathrm{~g})$. We must measure or know the $\Delta H_{f}^{\theta}$ values of $\mathrm{C}_{2} \mathrm{H}_{6}(\mathrm{~g}), \mathrm{O}_{2}(\mathrm{~g}), \mathrm{CO}_{2}(\mathrm{~g})$ and $\mathrm{H}_{2} \mathrm{O}(1)$ in their standard states.

## Example 2.2

Calculate $\Delta H_{r x n}^{\ominus}$ for the combustion of $\mathrm{C}_{2} \mathrm{H}_{6}(\mathrm{~g})$ using the direct method

## Answer:

The reaction is;

$$
\begin{aligned}
& \mathrm{C}_{2} \mathrm{H}_{6}(\mathrm{~g})+\frac{7}{2} \mathrm{O}_{2}(\mathrm{~g}) \rightarrow 2 \mathrm{CO}_{2}(\mathrm{~g})+3 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \\
& \Delta H_{r x n}^{\ominus}= {\left[2 \Delta H_{f\left[\mathrm{CO}_{2}(\mathrm{~g})\right]}^{\ominus}+3 \Delta H_{f\left[H_{2} \mathrm{O}(\mathrm{l})\right]}^{\ominus}\right]-\left[\Delta H_{f\left[\mathrm{C}_{2} H_{6}(\mathrm{~g})\right]}^{\ominus}+\frac{7}{2} \Delta H_{f[\mathrm{O}(\mathrm{~g})]}^{\ominus}\right] } \\
&= 2 \times-393.5 \mathrm{~kJ} \mathrm{~mol}^{-1}+3 \times-285.8 \mathrm{~kJ} \mathrm{~mol}^{-1}-\left(-84.7 \mathrm{~kJ} \mathrm{~mol}^{-1}+\frac{7}{2} \times 0.0 \mathrm{~kJ} \mathrm{~mol}^{-1}\right) \\
&=\mathbf{- 1 5 5 9 . 7 ~ k J ~ m o l}
\end{aligned}
$$

## The Indirect Method;

In many cases or reactions, compounds cannot be directly synthesized from their elements. In some cases, the reaction proceeds too slowly, or side reactions produce substances other than the desired compound. In these cases $\Delta H_{f}^{\theta}$ can be determined by an indirect approach of Hess law as described earlier.

## G.C.E. (A/L) CHEMISTRY : UNIT 5 Energetics

## Example 2.3

Calculate $\Delta H_{r x n}^{\ominus}$ for the combustion of $\mathrm{C}_{2} \mathrm{H}_{6}(\mathrm{~g})$ using the indirect method

## Answer:

This is use of simple Hess Law cycles that you are likely to come across.
In the cycle below, this reaction has been written horizontally, and the enthalpy of formation values are added to complete the cycle.

Hess law cycle for the reaction of $\mathrm{C}_{2} \mathrm{H}_{6}$ with $\mathrm{O}_{2}$.

And now for the calculation we can write down all the enthalpy changes which make up the two routes, and equate.

$$
\begin{gathered}
-84.7 \mathrm{~kJ} \mathrm{~mol}^{-1}+\Delta H^{\ominus}=2 \times-393.5 \mathrm{~kJ} \mathrm{~mol}^{-1}+3 \times-285.8 \mathrm{~kJ} \mathrm{~mol}^{-1} \\
\Delta H^{\ominus}=\mathbf{- 1 5 5 9 . 7} \mathbf{~ k J ~ m o l} \\
\hline \mathbf{1}
\end{gathered}
$$

### 2.3 Lattice enthalpy or enthalpy of formation of an ionic compound: Born-Haber cycle

We can predict which elements are likely to form stable ionic compounds based on ionization energy and electron gain enthalpy. Ionization energy and electron gain enthalpy are defined for processes occurring in the gas phase, but at 100 kPa ( 1 atm ) and $25^{\circ} \mathrm{C}$ all ionic compounds are solids. The solid state is a very different environment because each cation in a solid is surrounded by a specific number of anions, and vice versa. Thus the overall stability of a solid ionic compound depends on the interactions of all these ions and not merely on the interaction of a single cation with a single anion. A quantitative measure of the stability of any ionic solid is its lattice (dissociation) enthalpy, defined as the enthalpy change when one mole of a solid ionic compound is completely separated into its gaseous ions.

## G.C.E. (A/L) CHEMISTRY : UNIT 5 Energetics

Lattice (dissociation) enthalpy cannot be measured directly. However, if we know the structure and composition of an ionic compound, we can calculate the compound's lattice enthalpy by using Coulomb law, which states that the potential energy ( $E$ ) between two ions is directly proportional to the product of their charges and inversely proportional to the distance of separation between them (will not discuss here).

We can also determine lattice enthalpy indirectly, by assuming that the formation of an ionic compound takes place in a series of steps. This procedure, known as the BornHaber cycle, relates lattice enthalpies of ionic compounds to ionization energies, electron gain energies and other atomic and molecular properties. Basically, it is based on Hess law. The Born-Haber cycle defines the various steps that precede the formation of an ionic solid. We will illustrate its use to find the lattice (dissociation) enthalpy of lithium fluoride. Consider the reaction between lithium and fluorine.

$$
\mathrm{Li}(\mathrm{~s})+\frac{1}{2} \mathrm{~F}_{2}(\mathrm{~g}) \rightarrow \mathrm{LiF}(\mathrm{~s}) \quad \Delta H_{r x n}^{\ominus}=?
$$

The standard enthalpy change for this reaction is $-594.1 \mathrm{~kJ} \mathrm{~mol}^{-1}$ which is the standard enthalpy of formation of LiF. Considering the formation of LiF from its elements through five separate steps as described below. This pathway facilitates to analyze the energy (enthalpy) changes in ionic compound formation, with the help of Hess law.

1. Sublimation step to convert solid lithium to lithium vapour

$$
\operatorname{Li}(\mathrm{s}) \rightarrow \mathrm{Li}(\mathrm{~g})
$$

$$
\Delta H_{s u b}^{\ominus}=\Delta H_{1}^{\ominus}=155.2 \mathrm{~kJ} \mathrm{~mol}^{-1}
$$

2. Atomization of $\mathrm{F}_{2}(\mathrm{~g})$ to $\mathrm{F}(\mathrm{g})$

$$
{ }_{2}^{1} \mathrm{~F}_{2}(\mathrm{~g}) \rightarrow \mathrm{F}(\mathrm{~g})
$$

$$
\Delta H_{a t}^{\ominus}=\Delta H_{2}^{\ominus}=75.3 \mathrm{~kJ} \mathrm{~mol}^{-1}
$$

3. Ionization of gaseous Li atoms

$$
\operatorname{Li}(\mathrm{g}) \rightarrow \mathrm{Li}^{+}(\mathrm{g})+\mathrm{e}
$$

$$
\Delta H_{I E 1}^{\ominus}=\Delta H_{3}^{\ominus}=520 \mathrm{~kJ} \mathrm{~mol}^{-1}
$$

4. Formation of $\mathrm{F}^{-}$by capturing an electron

$$
\mathrm{F}(\mathrm{~g})+\mathrm{e} \rightarrow \mathrm{~F}^{-}(\mathrm{g})
$$

$$
\Delta H_{E G}^{\ominus}=\Delta H_{4}^{\ominus}=-328 \mathrm{~kJ} \mathrm{~mol}^{-1}
$$

5. Combination between $\mathrm{Li}^{+}(\mathrm{g})$ and $\mathrm{F}^{-}(\mathrm{g})$

$$
\mathrm{Li}^{+}(\mathrm{g})+\mathrm{F}^{-}(\mathrm{g}) \rightarrow \mathrm{LiF}(\mathrm{~s}) \quad \Delta \boldsymbol{H}_{\mathbf{5}}^{\ominus}=\boldsymbol{x} \mathbf{k J ~ m o l}^{\mathbf{- 1}}
$$

The lattice dissociation enthalpy of LiF is defined as

$$
\mathrm{LiF}(\mathrm{~s}) \rightarrow \mathrm{Li}^{+}(\mathrm{g})+\mathrm{F}^{-}{ }^{(\mathrm{g})} \quad \Delta \boldsymbol{H}_{L}^{\ominus}=-\Delta \boldsymbol{H}_{5}^{\ominus}=-\boldsymbol{x} \mathbf{k J ~ m o l}^{-1}
$$

The value of $\Delta H_{5}^{\theta}$ can be calculated by the following procedure. As the overall reaction has the standard enthalpy change, $\Delta H_{r x n}^{\circ}$ of $-594.1 \mathrm{~kJ} \mathrm{~mol}^{-1}$, we can write,

$$
\Delta H_{r x n}^{\ominus}=\Delta H_{1}^{\ominus}+\Delta H_{2}^{\ominus}+\Delta H_{3}^{\ominus}+\Delta H_{4}^{\ominus}+\Delta H_{5}^{\ominus}
$$

and by summing up reactions of 5 steps we get the overall reaction as ;

$$
\mathrm{Li}(\mathrm{~s})+\frac{1}{2} \mathrm{~F}_{2}(\mathrm{~g}) \rightarrow \mathrm{LiF}(\mathrm{~s})
$$

Therefore, $-594.1 \mathrm{~kJ} \mathrm{~mol}^{-1}=155.2 \mathrm{~kJ} \mathrm{~mol}^{-1}+75.3 \mathrm{~kJ} \mathrm{~mol}^{-1}+520 \mathrm{~kJ} \mathrm{~mol}^{-1}+\left(-328 \mathrm{~kJ} \mathrm{~mol}^{-1}\right)+\Delta H_{5}^{\theta}$

## G.C.E. (A/L) CHEMISTRY : UNIT 5 Energetics

$\Delta H_{5}^{\theta}=-1016.6 \mathbf{~ k J ~ m o l}^{-\mathbf{1}}$ and hence the lattice dissociation enthalpy of $\mathrm{LiF}(\mathrm{s})$ is $1016.6 \mathrm{~kJ} \mathrm{~mol}^{-1}$

The Figure 2.7 below summarizes the Born-Haber cycle for LiF. Steps 1, 2 and 3 all require the input of energy. On the other hand, steps 4 and 5 release energy. Because $\Delta H_{5}^{\theta}$ is a large negative quantity, the lattice dissociation enthalpy of LiF is a large positive quantity, which accounts for the stability of solid LiF. The greater the lattice dissociation enthalpy means that the more stable the ionic compound which exists. Keep in mind that lattice dissociation enthalpy is always a positive quantity because the separation of ions in a solid into ions in the gas phase is an endothermic process.

Figure 2.7 Born-Haber cycle of the above system $\left(\Delta H_{5}^{\theta}=-1016.6 \mathrm{~kJ} \mathrm{~mol}^{-1}\right.$ and hence the lattice dissociation enthalpy of $\operatorname{LiF}(\mathrm{s})$ is $1016.6 \mathrm{~kJ} \mathrm{~mol}^{-1}$ ). In (a) each process is shown separately while (b) show respective processes together.

### 2.4 Spontaneity of chemical reactions

Spontaneous processes; An important part of experimental chemistry deals with spontaneous reactions, that is, reactions that take place without having to continually supply energy from outside the system. Or we can describe that as once a spontaneous reaction starts it will go to completion until either the reactants are consumed or it enters a state of equilibrium if the products are not removed. It is also important to remember that the term spontaneous does not necessarily mean a fast reaction rate. Time is not a part of the thermodynamic definition of a spontaneous process. A spontaneous process may or may not happen immediately, or at all.

For example, the conversion of diamond to graphite is a spontaneous process at $25^{\circ} \mathrm{C}$ and a pressure of 100 kPa , even though this process is so slow that it cannot be observed in a human life time.

One goal of thermodynamics is to predict whether a reaction will take place when a given set of reactants is brought together. Thermodynamics only tells us whether or not the reaction will occur, but it tells us nothing about how fast.

The release of heat by a reaction was once thought to be an indication that the reaction was spontaneous. The sign of the enthalpy change, $\Delta H$ or $\Delta H^{\theta}$, by itself is not an adequate guide to spontaneity because while some spontaneous reactions are known to be exothermic ( $\Delta H^{\ominus}$ is -ve), many endothermic reactions ( $\Delta H^{\ominus}$ is +ve ) are known to be spontaneous as well.

In addition to the heat absorbed or released in a spontaneous process, another factor called entropy must be considered. Entropy is a measure of the disorder or randomness of a system. The entropy $(S)$ is a state function that increases in value as the disorder or randomness of the system increases. Entropy has the units $\mathbf{J ~ K}^{-1} \mathbf{m o l}^{\mathbf{- 1}}$.

A number of factors contribute to the entropy of a substance, such as the physical state, temperature, molecular size, intermolecular forces, and mixing. Here at this stage it is simply described with physical state and temperature.

Gases tend to have the highest entropies because the motion of gas particles is highly random. Liquids tend to have higher entropies than solids, which are much more restricted in their motions. At room temperature, one mole of $\mathrm{CO}_{2(\mathrm{~g})}$ has a much higher entropy than one mole of liquid water, which has a higher entropy than one mole of solid copper metal. The entropy of a substance increases with temperature because the translational and rotational motions of the molecules increase with temperature. Water at $50^{\circ} \mathrm{C}$ is higher in entropy than water at $25^{\circ} \mathrm{C}$.

## Standard entropy change of a chemical reaction

The standard entropy change of a reaction is denoted by the symbol $\Delta S_{r x n}^{\circ}$. It can be calculated from standard molar entropy (entropy content of one mole of substance under a standard state) values where each standard molar entropy value is multiplied by the stoichiometric coefficient in the balanced chemical equation.

$$
\Delta S_{r x n}^{\Theta}=\Sigma S^{\ominus} \text { (products) }-\Sigma S^{\ominus} \text { (reactants) }
$$

$\Delta S_{r x n}^{\theta}$ is the entropy change when pure (unmixed) reactants in their standard states are converted to pure (unmixed) products in their standard states. The sign of $\Delta S_{r x n}^{\theta}$ can often be estimated by taking into account the stoichiometry of a reaction and the

## G.C.E. (A/L) CHEMISTRY : UNIT 5 Energetics

physical states of reactants and products. If the total number of moles of gas increases when going from reactants to products, we can predict that the sign of $\Delta S_{r x n}^{\ominus}$ is positive. The entropy of products is higher than that of reactants. Conversely, if the number of moles of gaseous products is less than the number of moles of gaseous reactants then the sign of $\Delta S_{r x n}^{\ominus}$ is negative.

## Example 2.4

Hydrogen and oxygen react to form water vapor in a spontaneous reaction.

$$
2 \mathrm{H}_{2}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \rightarrow 2 \mathrm{H}_{2} \mathrm{O}(\mathrm{~g})
$$

Predict the sign of the entropy change for this reaction and calculate $\Delta S_{r x n}^{\ominus}$ at $25^{\circ} \mathrm{C}$.

## Answer:

When hydrogen and oxygen gas react to form water vapour, three moles of gas are converted into two moles of gas, for every mole of reaction. The total number of moles of gas decreases, so $\Delta S_{\mathrm{rxn}}^{\ominus}$ for this reaction should be negative.

Using standard molar entropy values to calculate the standard entropy;

$$
\begin{aligned}
\Delta S_{r x n}^{\ominus} & =S^{\ominus}(\text { products })-S^{\ominus}(\text { reactants }) \\
& =(2 \mathrm{~mol})\left(S^{\ominus}\left[\mathrm{H}_{2} \mathrm{O}(\mathrm{~g})\right]\right)-\left\{(2 \mathrm{~mol})\left(S^{\ominus}\left[\mathrm{H}_{2}(\mathrm{~g}]\right)\right)+(1 \mathrm{~mol})\left(S^{\ominus}\left[\mathrm{O}_{2(g)}\right)\right)\right\} \\
& =(2)\left(188.8 \mathrm{~J} \mathrm{~K}^{-1} \mathrm{~mol}^{-1}\right)-\left\{(2)\left(130.7 \mathrm{~J} \mathrm{~K}^{-1} \mathrm{~mol}^{-1}\right)+(1)\left(205.1 \mathrm{~J} \mathrm{~K}^{-1} \mathrm{~mol}^{-1}\right)\right\} \\
& =-88.9 \mathrm{~J} \mathrm{~K}^{-1} \mathrm{~mol}^{-1}
\end{aligned}
$$

The entropy change for this reaction is negative, as predicted based on the reaction stoichiometry.

For a reaction to occur spontaneously, both enthalpy, $\Delta H_{r x n}^{\circ}$ and entropy, $\Delta S_{r x n}^{\circ}$ should be considered. As we know, for a reaction we can simply say that the decrease in enthalpy and increase in entropy favour the reaction and hence the reaction occurs spontaneously. In addition following combinations can also be considered under some conditions of temperature.

$$
\begin{array}{ll}
\Delta H_{r x n}^{\ominus}-\mathrm{ve}, \Delta S_{r x n}^{\ominus}+v e & \text { Spontaneous at all temperatures } \\
\Delta H_{r x n}^{\theta}+\mathrm{ve}, \Delta S_{r x n}^{\ominus}+v e & \text { Spontaneous at high temperatures } \\
\Delta H_{r x n}^{\ominus}-\mathrm{ve}, \Delta S_{r x n}^{\ominus}-v e & \text { Spontaneous at low temperatures } \\
\Delta H_{r x n}^{\ominus}+\mathrm{ve}, \Delta S_{r x n}^{\ominus}-v e & \begin{array}{l}
\text { Not spontaneous at all temperatures (Reverse } \\
\end{array} \\
\text { reaction is spontaneous) }
\end{array}
$$

## G.C.E. (A/L) CHEMISTRY : UNIT 5 Energetics

## Gibbs free energy ( $G$ ) and spontaneity of a reaction

As we have seen, the spontaneity of a reaction is determined by both the entropy and enthalpy change of the system. The Gibbs free energy ( $\boldsymbol{G}$ ), or simply free energy, is a state function that combines enthalpy and entropy, where $T$ is the absolute temperature. $G$ is defined as follows:

$$
G=H-T S
$$

For a reaction occurring at constant temperature, the change in free energy is,

$$
\Delta G=\Delta H-T \Delta S
$$

For a reaction occurring at constant temperature and at standard state the change in free energy is,

$$
\Delta \boldsymbol{G}_{r x n}^{\ominus}=\Delta \boldsymbol{H}_{r x n}^{\ominus}-\boldsymbol{T} \Delta \boldsymbol{S}_{r x n}^{\ominus}
$$

Note: Sometimes $\Delta G_{r x n}^{\Theta}$ indicated as $\Delta G_{r}^{\Theta}$.

- A reaction that is at equilibrium has $\Delta \boldsymbol{G}_{r x n}^{\ominus}=\mathbf{0}$. There will be no net change in either the forward or reverse direction. For a spontaneous reaction at constant temperature and pressure, $\Delta \boldsymbol{G}_{r x n}^{\ominus}<\mathbf{0}$, and for non-spontaneous reaction $\Delta \boldsymbol{G}_{r x n}^{\ominus}>\mathbf{0}$.

## Example 2.5

Carbon monoxide and oxygen gas react to form carbon dioxide.

$$
\mathrm{CO}(\mathrm{~g})+1 / 2 \mathrm{O}_{2}(\mathrm{~g}) \rightarrow \mathrm{CO}_{2}(\mathrm{~g})
$$

Calculate the standard free energy change for this reaction at $25^{\circ} \mathrm{C}$ from $\Delta H_{r x n}^{\theta}$ and $\Delta S_{r x n}^{\ominus}$.
$\left(\Delta H_{f}^{\theta}\left[\mathrm{CO}_{2}(\mathrm{~g})\right]=-393.5 \mathrm{~kJ} \mathrm{~mol}^{-1}, \Delta H_{f}^{\theta}[\mathrm{CO}(\mathrm{g})]=-110.5 \mathrm{~kJ} \mathrm{~mol}^{-1}, S^{\Theta}\left[\mathrm{CO}_{2}(\mathrm{~g})\right]=213.7 \mathrm{~J} \mathrm{~mol}^{-1} \mathrm{~K}^{-1}\right.$, $\left.S^{\theta}[\mathrm{CO}(\mathrm{g})]=197.7 \mathrm{~J} \mathrm{~mol}^{-1} \mathrm{~K}^{-1}, S^{\Theta}\left[\mathrm{O}_{2}(\mathrm{~g})\right]=205.1 \mathrm{~J} \mathrm{~mol}^{-1} \mathrm{~K}^{-1}\right)$

## Answer:

Using the standard heats of formation calculate first the enthalpy change for this reaction under standard state conditions.

$$
\begin{aligned}
\Delta H_{r x n}^{\ominus} & =\Delta H_{f}^{\ominus}(\text { products })-\Delta H_{f}^{\ominus}(\text { reactants }) \\
& =\Delta H_{f}^{\ominus}\left[\mathrm{CO}_{2}(\mathrm{~g})\right]-\Delta H_{f}^{\ominus}[\mathrm{CO}(\mathrm{~g})]-1 / 2 \Delta H_{f}^{\ominus}\left[\mathrm{O}_{2}(\mathrm{~g})\right] \\
& =-393.5 \mathrm{~kJ} \mathrm{~mol}^{-1}-\left(-110.5 \mathrm{~kJ} \mathrm{~mol}^{-1}\right)-0 \mathrm{~kJ} \mathrm{~mol}^{-1} \\
& =-283.0 \mathrm{~kJ} \mathrm{~mol}^{-1}
\end{aligned}
$$

Using standard entropy values calculate the entropy change for this reaction under standard state conditions.

$$
\begin{aligned}
\Delta S_{r x n}^{\ominus} & =S^{\ominus}(\text { products })-S^{\ominus} \text { (reactants) } \\
& =S^{\ominus}\left[\mathrm{CO}_{2}(\mathrm{~g})\right]-S^{\ominus}[C O(\mathrm{~g})]-1 / 2 S^{\ominus}\left[\mathrm{O}_{2}(\mathrm{~g})\right] \\
& =213.7 \mathrm{~J} \mathrm{~mol}^{-1} \mathrm{~K}^{-1}-\left(197.7 \mathrm{~J} \mathrm{~mol}^{-1} \mathrm{~K}^{-1}\right)-(1 / 2)\left(205.1 \mathrm{~J} \mathrm{~mol}^{-1} \mathrm{~K}^{-1}\right) \\
& =-86.6 \mathrm{~J} \mathrm{~mol}^{-1} \mathrm{~K}^{-1}
\end{aligned}
$$

Note: $\Delta S_{r x n}^{\ominus}$ is negative, as predicted by the stoichiometry: 1.5 moles of gas forms 1 mole of gas.

Calculate $\Delta G_{r x n}^{\ominus}$ using

$$
\begin{aligned}
\Delta G_{r x n}^{\ominus} & =\Delta H_{r x n}^{\ominus}-T \Delta S_{r x n}^{\ominus} \\
& =-283.0 \mathrm{~kJ} \mathrm{~mol}^{-1}-(298 \mathrm{~K})\left(-86.6 \mathrm{~J} \mathrm{~mol}^{-1} \mathrm{~K}^{-1}\right)(1 \mathrm{~kJ} / 1000 \mathrm{~J}) \\
& =-257 \mathrm{~kJ} \mathrm{~mol}^{-1}
\end{aligned}
$$

$\Delta G_{r x n}^{\ominus}$ is negative. Therefore, the reaction occurs spontaneously.

Table 2.2 A summary

| Relationships |  | Units |
| :---: | :---: | :---: |
| Enthalpy change of reaction | $\Delta H=\Sigma v_{p} H_{\text {(products) }}-v_{r} \Sigma H_{\text {(reactants) }}$ | $\mathrm{kJ} \mathrm{mol}^{-1}$ |
| Standard enthalpy change of a reaction | $\Delta H_{r x n}^{\Theta}=\sum v_{p} H_{f[\text { products }]}^{\Theta}-\sum v_{r} H_{f[\text { reactants }]}^{\Theta}$ <br> (Where $v_{p}$ and $v_{r}$ are the stoichiometric coefficients of products and reactants) | $\mathrm{kJ} \mathrm{~mol}^{-1}$ |
| Hess Law | In other words, Hess law is simply a consequence of the state function property enthalpy. Regardless of the path taken in going from the initial state to the final state, $\Delta H$ (or $\Delta H^{\theta}$ ) if the process is carried out under standard conditions) has the same value or it is independent of the route. |  |
| Standard entropy change for a reaction | $\Delta S_{r x n}^{\theta}=\Sigma v_{p} S^{\theta}$ (products) $-\Sigma v_{r} S^{\theta}$ (reactants) | $\mathrm{J} \mathrm{K}^{-1} \mathrm{~mol}^{-1}$ |
| Standard change in free energy | $\Delta G_{r x n}^{\ominus}=\Delta H_{r x n}^{\ominus}-T \Delta S_{r x n}^{\ominus}$ | $\mathrm{kJ} \mathrm{mol}^{-1}$ |
| Spontaneity of a reaction | Spontaneous at all temperatures | $\begin{aligned} & \Delta H_{r x n}^{\ominus} \text {-ve } \\ & \Delta S_{r x n}^{\theta}+v e \end{aligned}$ |
|  | Spontaneous at high temperatures | $\begin{aligned} & \Delta H_{r x n}^{\theta}+\mathrm{ve} \\ & \Delta S_{r x n}^{\theta}+v e \end{aligned}$ |
|  | Spontaneous at low temperatures | $\begin{aligned} & \Delta H_{r x n}^{\theta} \text {-ve } \\ & \Delta S_{r x n}^{\theta}-v e \end{aligned}$ |
|  | Not spontaneous at all temperatures (Reverse reaction is spontaneous) | $\begin{aligned} & \Delta H_{r x n}^{\theta}+\mathrm{ve} \\ & \Delta S_{r x n}^{\theta}-v e \\ & \hline \end{aligned}$ |
|  | Spontaneous | $\Delta G_{r x n}^{\theta}<0$ |
|  | Not spontaneous | $\Delta G_{r x n}^{\ominus}>0$ |
|  | Equilibrium | $\Delta G_{r x n}^{\theta}=0$ |

## Message from the Director General

The National Institute of Education takes opportune steps from time to time for the development of quality in education. Preparation of supplementary resource books for respective subjects is one such initiative.

Supplementary resource books have been composed by a team of curriculum developers of the National Institute of Education, subject experts from the national universities and experienced teachers from the school system. Because these resource books have been written so that they are in line with the G. C. E. (A/L) new syllabus implemented in 2017, students can broaden their understanding of the subject matter by referring these books while teachers can refer them in order to plan more effective learning teaching activities.

I wish to express my sincere gratitude to the staff members of the National Institute of Education and external subject experts who made their academic contribution to make this material available to you.

Dr. (Mrs.) T. A. R. J. Gunasekara

Director General
National Institute of Education
Maharagama.

## Message from the Director

Since 2017, a rationalized curriculum, which is an updated version of the previous curriculum is in effect for the G.C.E (A/L) in the general education system of Sri Lanka. In this new curriculum cycle, revisions were made in the subject content, mode of delivery and curricular materials of the G.C.E. (A/L) Physics, Chemistry and Biology. Several alterations in the learning teaching sequence were also made. A new Teachers’ Guide was introduced in place of the previous Teacher's Instruction Manual. In concurrence to that, certain changes in the learning teaching methodology, evaluation and assessment are expected. The newly introduced Teachers' Guide provides learning outcomes, a guideline for teachers to mould the learning events, assessment and evaluation.

When implementing the previous curricula, the use of internationally recognized standard textbooks published in English was imperative for the Advanced Level science subjects. Due to the contradictions of facts related to the subject matter between different textbooks and inclusion of the content beyond the limits of the local curriculum, the usage of those books was not convenient for both teachers and students. This book comes to you as an attempt to overcome that issue.

As this book is available in Sinhala, Tamil, and English, the book offers students an opportunity to refer the relevant subject content in their mother tongue as well as in English within the limits of the local curriculum. It also provides both students and teachers a source of reliable information expected by the curriculum instead of various information gathered from the other sources.

This book authored by subject experts from the universities and experienced subject teachers is presented to you followed by the approval of the Academic Affairs Board and the Council of the National Institute of Education. Thus, it can be recommended as a material of high standard.

## Introduction

This section describes the physical and chemical properties of elements in $s, p$ and $d$ blocks. This section will help to identify trends and patterns among elements in the periodic table.

## $s$ Block Elements

### 4.1 Group 1 elements

All Group 1 elements are metals except hydrogen which is a nonmetal. Unlike most other metals, they have low densities. All Group 1 elements have the valence shell electron configuration of $n s^{1}$ therefore, they are highly reactive.

Sodium can be found naturally as various salts such as NaCl (rock salt) and $\mathrm{Na}_{2} \mathrm{~B}_{4} \mathrm{O}_{7} \cdot 10 \mathrm{H}_{2} \mathrm{O}$ (borax). Some examples of naturally occurring potassium salts are KCl (sylvite) and $\mathrm{KCl} \cdot \mathrm{MgCl}_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}$ (carnallite).

### 4.1.1 Group trends

All alkali metals are lustrous. They are high electrical and thermal conductors. These metals are soft and become even softer when progress down the group. The melting point of Group 1 metals decreases down the group. The values given in Table 4.1 below can be used to understand the trends among these elements. Group 1 metals always show oxidation number of +1 when they form compounds. Most compounds are stable ionic solids.

Table 4.1 Properties of Group 1 elements

|  | Li | Na | K | Rb | Cs |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Ground state electronic configuration | [He] $2 s^{1}$ | $[\mathrm{Ne}] 3{ }^{1}$ | [Ar] ${ }^{1}{ }^{1}$ | [Kr]5s ${ }^{1}$ | [Xe] $6 s^{1}$ |
| Metallic radius/ pm | 152 | 186 | 231 | 244 | 262 |
| Melting point $/{ }^{\circ} \mathrm{C}$ | 180 | 98 | 64 | 39 | 29 |
| Radius of $\mathrm{M}^{+}$/ pm | 60 | 95 | 133 | 148 | 169 |
| $11^{\text {st }}$ ionization energy/ $\mathrm{kJ} \mathrm{mol}^{-1}$ | 520 | 495 | 418 | 403 | 375 |
| $2{ }^{\text {nd }}$ ionization energy/ $\mathrm{kJ} \mathrm{mol}^{-1}$ | 7298 | 4562 | 3052 | 2633 | 2234 |

Increase in the atomic radius from Li to Cs makes the ionization energy of these elements to decrease down the group, and this can be used to explain the chemical properties of Group 1 elements. Reactivity of the Group 1 elements increases down the group.
** When writing equations in inorganic chemistry, it is not always essential to indicate the physical state of reactants or products. However, always balance equations must be written to consider as a complete answer.

### 4.1.2 Reactions of Group 1 elements

| With oxygen $\left(\mathrm{O}_{2}\right)$ | $4 \mathrm{M}+\mathrm{O}_{2}$ | $\longrightarrow$ | $2 \mathrm{M}_{2} \mathrm{O}$ |
| :--- | :--- | :--- | :--- |
| With excess oxygen $\left(\mathrm{O}_{2}\right)$ Na form peroxides | $2 \mathrm{Na}+\mathrm{O}_{2}$ | $\longrightarrow$ | $\mathrm{Na}_{2} \mathrm{O}_{2}$ |
| With excess oxygen $\left(\mathrm{O}_{2}\right) \mathrm{K}, \mathrm{Rb}$ and Cs form <br> superoxides | $\mathrm{M}+\mathrm{O}_{2}$ | $\longrightarrow$ | $\mathrm{MO}_{2}$ |
| With nitrogen $\left(\mathrm{N}_{2}\right)$ only Li forms stable <br> nitride | $6 \mathrm{Li}+\mathrm{N}_{2}$ | $\longrightarrow$ | $2 \mathrm{Li}_{3} \mathrm{~N}$ |
| With hydrogen $\left(\mathrm{H}_{2}\right)$ | $2 \mathrm{M}+\mathrm{H}_{2}$ | $\longrightarrow$ | 2 MH |
| With water $\left(\mathrm{H}_{2} \mathrm{O}\right)$ | $2 \mathrm{M}+2 \mathrm{H}_{2} \mathrm{O}$ | $\longrightarrow$ | $2 \mathrm{MOH}+\mathrm{H}_{2}$ |
| With acids $\left(\mathrm{H}^{+}\right)$ | $2 \mathrm{M}+2 \mathrm{H}^{+}$ | $\longrightarrow$ | $2 \mathrm{M}^{+}+\mathrm{H}_{2}$ |

## Reaction with water

Group 1 metals show an increase in reactivity with water down the group. The reactivity trend with water is as follows.

| $\mathbf{L i}$ | $\mathbf{N a}$ | $\mathbf{K}$ | $\mathbf{R b}$ | $\mathbf{C s}$ |
| :--- | :--- | :--- | :--- | :--- |
| Gently | Vigorously | Vigourously <br> with ignition | Explosively | Explosively |

Lithium reacts non-vigorously with water or with water vapour available in the air to produce lithium hydroxide and hydrogen gas. However, both sodium and potassium react vigorously with water to produce metal hydroxide and hydrogen gas. These reactions are highly exothermic except with Li.

## Reactions with oxygen/ air

Lithium can react both with oxygen and nitrogen. When heated, lithium burns to produce lithium oxide $\left(\mathrm{Li}_{2} \mathrm{O}\right)$, a white powder. With nitrogen gas, lithium gives lithium nitride $\left(\mathrm{Li}_{3} \mathrm{~N}\right)$. However, both sodium and potassium do not react with nitrogen gas. When sodium is burnt in air, sodium peroxide is mainly produced with some sodium oxide. In contrast, when potassium is burnt in air, potassium superoxide is formed as the main product with some potassium oxide and peroxide. Oxidation numbers of oxygen in sodium or potassium peroxide are -1 and in potassium superoxide, oxidation numbers are -1 and 0 .

Group 1 metal oxides react with water to produce metal hydroxides as shown below.

$$
\mathrm{Na}_{2} \mathrm{O}(\mathrm{~s})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow 2 \mathrm{NaOH}(\mathrm{aq})
$$

When heated, lithium forms lithium nitride with nitrogen. Only lithium forms a stable alkali-metal nitride. With water, lithium nitride produces ammonia and lithium hydroxide.

$$
\mathrm{Li}_{3} \mathrm{~N}(\mathrm{~s})+3 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow 3 \mathrm{LiOH}(\mathrm{aq})+\mathrm{NH}_{3}(\mathrm{~g})
$$

Group 1 hydroxides react with carbon dioxide to produce relevant carbonates. These carbonates can further react with carbon dioxide to produce metal hydrogen carbonates.

$$
\begin{aligned}
& 2 \mathrm{NaOH}(\mathrm{aq})+\mathrm{CO}_{2}(\mathrm{~g}) \longrightarrow \mathrm{Na}_{2} \mathrm{CO}_{3}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \\
& \mathrm{Na}_{2} \mathrm{CO}_{3}(\mathrm{aq})+\mathrm{CO}_{2}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow 2 \mathrm{NaHCO}_{3}(\mathrm{~s})
\end{aligned}
$$

Sodium hydrogen carbonate is less soluble than sodium carbonates in water.

## Reactions with hydrogen gas

Group 1 elements react with hydrogen to produce solid, ionic metal hydrides. In these hydrides, hydrogen has the oxidation number of -1 . These metal hydrides react vigorously with water to produce hydrogen gas.

$$
\begin{aligned}
& 2 \mathrm{Na}(\mathrm{~s})+\mathrm{H}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{NaH}(\mathrm{~s}) \\
& \mathrm{NaH}(\mathrm{~s})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow \mathrm{NaOH}(\mathrm{aq})+\mathrm{H}_{2}(\mathrm{~g})
\end{aligned}
$$

## Reactions with acids

Lithium, sodium and potassium react vigorously with dilute acids to produce hydrogen gas and relevant metal salts. These reactions are highly exothermic and explosive. A few selected reactions are shown below.

$$
\begin{aligned}
& 2 \mathrm{Li}(\mathrm{~s})+\text { dil. } 2 \mathrm{HNO}_{3}(\mathrm{aq}) \longrightarrow 2 \mathrm{LiNO}_{3}(\mathrm{aq})+\mathrm{H}_{2}(\mathrm{~g}) \\
& 2 \mathrm{Na}(\mathrm{~s})+\text { dil. } \mathrm{H}_{2} \mathrm{SO}_{4}(\mathrm{aq}) \longrightarrow \mathrm{Na}_{2} \mathrm{SO}_{4}(\mathrm{aq})+\mathrm{H}_{2}(\mathrm{~g})
\end{aligned}
$$

### 4.1.3 Thermal stability of salts

## Decomposition of nitrates

Group 1 nitrates are used as fertilizers and explosives. These nitrates decompose upon heating. $\mathrm{LiNO}_{3}$ decomposes to produce lithium oxide, nitrogen dioxide and oxygen. However, the other Group 1 nitrates on heating produce relevant metal nitrite and oxygen.

## Decomposition of carbonates

Carbonates are stable and they will melt before they decompose into oxides. However, $\mathrm{Li}_{2} \mathrm{CO}_{3}$ is less stable and decomposes readily.

$$
\mathrm{Li}_{2} \mathrm{CO}_{3}(\mathrm{~s}) \xrightarrow{\Delta} \mathrm{Li}_{2} \mathrm{O}(\mathrm{~s})+\mathrm{CO}_{2}(\mathrm{~g})
$$

## Decomposition of bicarbonates

Decomposition of bicarbonates of Group 1 is shown below.

$$
2 \mathrm{NaHCO}_{3}(\mathrm{~s}) \xrightarrow{\Delta} \mathrm{Na}_{2} \mathrm{CO}_{3}(\mathrm{~s})+\mathrm{H}_{2} \mathrm{O}(\mathrm{~g})+\mathrm{CO}_{2}(\mathrm{~g})
$$

Thermal stability increases down the group.

### 4.1.4 Solubility of Group 1 salts

All Group 1 salts are soluble in water except some lithium salts such as $\mathrm{LiF}, \mathrm{Li}_{2} \mathrm{CO}_{3}$ and $\mathrm{Li}_{3} \mathrm{PO}_{4}$. All these salts are white solids unless the salt anion is a coloured ion.

Solubility of Group 1 halides increase down the group is shown in Table 4.2.
Table 4.2 The solubility of halides of sodium

| Salt | Solubility/ mol L ${ }^{-1}$ |
| :--- | :--- |
| NaF | 0.99 |
| NaCl | 6.2 |
| NaBr | 9.2 |
| NaI | 12.3 |

Variation in the solubility can be understood using the energy cycle for the solvation of ionic solids. The solubility can be explained using Gibbs free energy. For almost all ionic solids of Group 1, are soluble in water due to the negative Gibbs free energy in the solvation process.

Enthalpy and entropy cycles for the solvation process are shown below.

Figure 4.1 Enthalpy and entropy cycles for the solvation process
Using these two energy cycles, enthalpy and entropy change of solvation can be calculated and these calculated values are given in Table 4.3. Free energy is calculated using the equation,

$$
\Delta G^{\theta}=\Delta H^{\theta}-\mathrm{T} \Delta S^{\theta}
$$

Table 4.3 Free energy change of salts during solvation

| Salt | Enthalpy change/ <br> $\mathbf{k J ~ m o l}$ <br> $\mathbf{- 1}$ | Entropy change $\times \mathbf{T}$ <br> $\left(\mathbf{K} \times \mathbf{k J ~ m o l}^{\mathbf{- 1}} \mathbf{K}^{\mathbf{- 1}}\right)$ | Free energy change/ <br> $\mathbf{k J} \mathbf{~ m o l}^{\mathbf{- 1}}$ |
| :--- | :--- | :--- | :--- |
| NaF | +1 | -2 | +3 |
| NaCl | +4 | +13 | -9 |
| NaBr | -1 | +18 | -19 |
| NaI | -9 | +23 | -32 |

Calculated Gibbs free energies match with the solubility trend for the sodium halides. The free energy change gets more negative from sodium fluoride to sodium iodide.

### 4.1.5 Flame test

The flame test can be used to identify alkali metals and their compounds. Flame colours of Group 1 metals and compounds are given below.

$$
\begin{array}{ll}
\text { Lithium - Crimson red } & \text { Sodium }- \text { Yellow } \\
\text { Rubidium - Red-violet } & \text { Caesium - Blue - violet } \\
\text { Potassium - Lilac } &
\end{array}
$$

### 4.2 Group 2 elements

Group 2 elements are known as alkaline earth metals. They are less reactive than Group 1 metals due to its valence shell $\mathrm{ns}^{2}$ electron configuration.

Both calcium and magnesium can be found naturally in dolomite $\left(\mathrm{CaCO}_{3} \cdot \mathrm{MgCO}_{3}\right)$. Magnesite $\left(\mathrm{MgCO}_{3}\right)$, kieserite $\left(\mathrm{MgSO}_{4} \cdot \mathrm{H}_{2} \mathrm{O}\right)$ and carnallite $\left(\mathrm{KMgCl}_{3} \cdot 6 \mathrm{H}_{2} \mathrm{O}\right)$ are
examples of minerals with magnesium. Fluoroapatite $\left[3\left(\mathrm{Ca}_{3}\left(\mathrm{PO}_{4}\right)_{2}\right) \cdot \mathrm{CaF}_{2}\right]$ and gypsum $\left(\mathrm{CaSO}_{4} \cdot 2 \mathrm{H}_{2} \mathrm{O}\right)$ are commercially important calcium contacting minerals.

### 4.2.1 Group trends

Beryllium and magnesium are greyish metals and other Group 2 metals are soft and silvery in colour. Group 2 metal oxides produce basic oxides except for BeO which shows amphoteric properties. Beryllium behaves similar to Al and this can be understood using the diagonal relationship between Al and Be in the periodic table.

Elements of Group 2 have higher densities and stronger metallic bonds compared to the Group 1 metals. This is due to the availability of a greater number of electrons to form a stronger metallic bond and their smaller size in atomic radii.

The first ionization energies of Group 2 elements are higher than that of Group 1 elements due to their electron configuration of $n s^{2}$. Elements become more reactive and produce +2 oxidation state easily down the group. The properties of Group 2 elements are given in Table 4.4.

Table 4.4 Properties of Group 2 elements

|  | Be | Mg | Ca | Sr | Ba |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Ground state electronic configuration | $[\mathrm{He}] 2 s^{2}$ | $[\mathrm{Ne}] 3 \mathrm{~s}^{2}$ | $[\mathrm{Ar}] 4 \mathrm{~s}^{2}$ | $[\mathrm{Kr}] 5 \mathrm{~s}^{2}$ | [Xe]6s ${ }^{2}$ |
| Metallic radius/ pm | 112 | 160 | 197 | 215 | 224 |
| Melting point $/{ }^{\circ} \mathrm{C}$ | 1560 | 923 | 1115 | 1040 | 973 |
| Radius of $\mathrm{M}^{2+} / \mathrm{pm}$ | 30 | 65 | 99 | 113 | 135 |

### 4.2.2 Reactions of alkaline earth Group 2 elements

| With oxygen ( $\mathrm{O}_{2}$ ) | $2 \mathrm{M}+\mathrm{O}_{2} \longrightarrow 2 \mathrm{MO}$ |
| :---: | :---: |
| With excess oxygen $\left(\mathrm{O}_{2}\right) \mathrm{Ba}$ forms its peroxide | $\mathrm{Ba}+\mathrm{O}_{2} \longrightarrow \mathrm{BaO}_{2}$ |
| With nitrogen $\left(\mathrm{N}_{2}\right)$, at high temperatures | $3 \mathrm{M}+\mathrm{N}_{2} \longrightarrow \mathrm{M}_{3} \mathrm{~N}_{2}$ |
| With water $\left(\mathrm{H}_{2} \mathrm{O}(\mathrm{l})\right)$, at room temperature (e.g.: $\mathrm{Ca}, \mathrm{Sr}$ and Ba ) | $\mathrm{M}+2 \mathrm{H}_{2} \mathrm{O} \longrightarrow \mathrm{M}(\mathrm{OH})_{2}+\mathrm{H}_{2}$ |
| With hot water $\left(\mathrm{H}_{2} \mathrm{O}(\mathrm{l})\right)$ (e.g.: Mg reacts slow) | $\mathrm{Mg}+2 \mathrm{H}_{2} \mathrm{O} \longrightarrow \mathrm{Mg}(\mathrm{OH})_{2}+\mathrm{H}_{2}$ |
| With steam ( $\mathrm{H}_{2} \mathrm{O}(\mathrm{g})$ ) | $\mathrm{Mg}+\mathrm{H}_{2} \mathrm{O} \longrightarrow \mathrm{MgO}+\mathrm{H}_{2}$ |
| With acids ( $\mathrm{H}^{+}$) | $\mathrm{M}+2 \mathrm{H}^{+} \longrightarrow \mathrm{M}^{2+}+\mathrm{H}_{2}$ |
| With hydrogen $\left(\mathrm{H}_{2}\right)$, at high temperatures with $\mathrm{Ca}, \mathrm{Sr}, \mathrm{Ba}$ at high pressure with Mg | $\mathrm{M}+\mathrm{H}_{2} \longrightarrow \mathrm{MH}_{2}$ |
| With concentrated acids | $\begin{aligned} & \mathrm{Mg}+2 \mathrm{H}_{2} \mathrm{SO}_{4} \longrightarrow \mathrm{MgSO}_{4}+\mathrm{SO}_{2}+2 \mathrm{H}_{2} \mathrm{O} \\ & \mathrm{Mg}+4 \mathrm{HNO}_{3} \longrightarrow \mathrm{Mg}\left(\mathrm{NO}_{3}\right)_{2}+2 \mathrm{NO}_{2}+2 \mathrm{H}_{2} \mathrm{O} \end{aligned}$ |

## Reaction with water

Beryllium does not react with water, but it reacts with steam. The reaction of magnesium with water at room temperature is negligible. However, magnesium reacts slowly with hot water. Calcium, strontium and barium react readily with cold water. Reaction with water produces metal hydroxide and hydrogen gas.

$$
\mathrm{Ca}(\mathrm{~s})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow \mathrm{Ca}(\mathrm{OH})_{2}(\mathrm{aq})+\mathrm{H}_{2}(\mathrm{~g})
$$

## Reactions with hydrogen

All Group 2 elements, except Be, react with hydrogen to produce metal hydrides which are ionic solids. In these hydrides, hydrogen has an oxidation number of -1 . These metal hydrides (not violent as Group 1) react vigorously with water to produce hydrogen gas.

$$
\begin{aligned}
& \mathrm{Ca}(\mathrm{~s})+\mathrm{H}_{2}(\mathrm{~g}) \longrightarrow \mathrm{CaH}_{2}(\mathrm{~s}) \\
& \mathrm{CaH}_{2}(\mathrm{~s})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow \mathrm{Ca}(\mathrm{OH})_{2}(\mathrm{aq})+2 \mathrm{H}_{2}(\mathrm{~g})
\end{aligned}
$$

## Reaction with nitrogen

All Group 2 elements burns in nitrogen to form $\mathrm{M}_{3} \mathrm{~N}_{2}$, nitrides. These nitrides react with water to produce ammonia in the same way as lithium does.

$$
\begin{aligned}
& 3 \mathrm{Mg}(\mathrm{~s})+\mathrm{N}_{2}(\mathrm{~g}) \longrightarrow \mathrm{Mg}_{3} \mathrm{~N}_{2}(\mathrm{~s}) \\
& \mathrm{Mg}_{3} \mathrm{~N}_{2}(\mathrm{~s})+6 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow 3 \mathrm{Mg}(\mathrm{OH})_{2}(\mathrm{aq})+2 \mathrm{NH}_{3}(\mathrm{~g})
\end{aligned}
$$

### 4.2.3 Thermal stability of salts

## Decomposition of nitrates

Upon heating, Group 2 nitrates behave much similar to lithium nitrate. Group 2 nitrates decompose to produce metal oxide, nitrogen dioxide and oxygen. All Group 2 nitrates are soluble in water.

$$
2 \mathrm{Mg}\left(\mathrm{NO}_{3}\right)_{2}(\mathrm{~s}) \longrightarrow 2 \mathrm{MgO}(\mathrm{~s})+4 \mathrm{NO}_{2}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g})
$$

## Decomposition of carbonates

Thermal stability of these carbonates increases down the group. Thermal stability of these carbonates increases with the size of the cation. The polarizing power of the cation decreases down the group due to the decrease of charge density of the cation. Carbonate anion attached to $\mathrm{Mg}^{2+}$ cation is highly polarized than that of carbonate attached to $\mathrm{Ba}^{2+}$. Highly polarized carbonate anion can undergo decomposition easily and this explains the lower decomposition temperature of $\mathrm{MgCO}_{3}$ than that of $\mathrm{BaCO}_{3}$. The general decomposition of metal carbonates is shown below.

$$
\mathrm{MCO}_{3} \longrightarrow \mathrm{MO}+\mathrm{CO}_{2}
$$

Decomposition temperature increases from $540^{\circ} \mathrm{C}$ for $\mathrm{MgCO}_{3}$ to $1360{ }^{\circ} \mathrm{C}$ for $\mathrm{BaCO}_{3}$.

## Decomposition of bicarbonates

Group 2 hydrogen carbonates are only stable in aqueous solutions and solid Group 2 hydrogen carbonates are not stable at room temperature.

$$
\mathrm{Ca}\left(\mathrm{HCO}_{3}\right)_{2}(\mathrm{aq}) \longrightarrow \mathrm{CaCO}_{3}(\mathrm{~s})+\mathrm{CO}_{2}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

### 4.2.4 Solubility of Group 2 salts

Solubility of Group 2 changes depending on the compound. Some compounds such as nitrate, nitrite, halides, hydroxides, sulphides, bicarbonates all are soluble in water. The solubility varies down the group for certain compounds such as hydroxides, sulphate, sulphite, carbonate, phosphate and oxalate showing the patterns given in Table 4.5.

Salts of Group 2 metals with uninegative anions, such as chloride and nitrates are generally soluble. However, salts formed with anions containing more than one negative charge, such as carbonates and phosphates, are insoluble. All carbonates are insoluble except $\mathrm{BeCO}_{3}$. Hydrogen carbonates are more soluble than carbonates. The solubility of Group 2 sulphates changes from soluble to insoluble when comparing solubility from $\mathrm{MgSO}_{4}$ to $\mathrm{BaSO}_{4}$. On the other hand, hydroxides change solubility from insoluble to soluble when moving down the group. For example, $\mathrm{Mg}(\mathrm{OH})_{2}$ is sparingly soluble whereas $\mathrm{Ba}(\mathrm{OH})_{2}$ is soluble and produces a strongly basic solution.

Table 4.5 Solubility of Group 1 and 2 compounds

### 4.2.5 Flame test

Alkaline earth metals and compounds produce characteristic colours with the flame, and the flame test can be used to identify these elements using the flame colors shown below.

$$
\text { Calcium - Orange-red } \quad \text { Strontium - Crimson red } \quad \text { Barium - Yellowish-green }
$$

## p Block Elements

### 4.3 Group 13 elements

### 4.3.1 Group trends

Boron is a metalloid, and most of the boron compounds are covalent. However, aluminium is a metal with amphoteric properties. Gallium, indium and thallium are metals. The first member, B, of Group 13 is different from the other members due to its smaller atomic radius. Boron shows a strong diagonal relationship with Si in Group 14. All elements in Group 13 produce +3 oxidation state. The properties of Group 13 elements are given in Table 4.6.

Table 4.6 Properties of Group 13 elements

|  | **B | Al | **Ga | **In | **T1 |
| :---: | :---: | :---: | :---: | :---: | :---: |

| $\begin{aligned} & \hline 2^{\text {nd }} \text { ionization energy/ } \\ & \mathrm{kJ} \mathrm{~mol}^{-1} \end{aligned}$ | 2427 | 1817 | 1979 | 1821 | 1971 |
| $\begin{aligned} & \hline 3^{\text {rd }} \text { ionization energy/ } \\ & \mathrm{kJ} \mathrm{~mol}^{-1} \end{aligned}$ | 3660 | 2745 | 2963 | 2704 | 2878 |

**Not a part of current G. C. E. (A/L) syllabus

### 4.3.2 Aluminium

Aluminium is the third most abundant element in the earth crust. The exposed surface of aluminium produces a layer of $\mathrm{Al}_{2} \mathrm{O}_{3}$. This layer makes aluminium resistant to further reactions with oxygen. Due to this impermeable layer, Al can be considered as a nonreactive element with air.

## Reactions of aluminium

Aluminium reacts readily with $\mathrm{O}_{2}$ and halogens. Also, it reacts with $\mathrm{N}_{2}$.

$$
\begin{aligned}
& \text { With oxygen }\left(\mathrm{O}_{2}\right): 4 \mathrm{Al}+\mathrm{O}_{2} \longrightarrow 2 \mathrm{Al}_{2} \mathrm{O}_{3} \\
& \text { With halogen }\left(\mathrm{X}_{2}\right): 2 \mathrm{Al}+3 \mathrm{X}_{2} \longrightarrow 2 \mathrm{AlX}_{3}
\end{aligned}
$$

$$
\text { With nitrogen }\left(\mathrm{N}_{2}\right): 2 \mathrm{Al}+\mathrm{N}_{2} \longrightarrow 2 \mathrm{AlN}
$$

Aluminum is less reactive than Groups 1 and 2 elements. Similar to beryllium, aluminium reacts with both acids and bases. The equations for the reactions of Al with acids and bases are given below.

$$
\begin{aligned}
& 2 \mathrm{Al}(\mathrm{~s})+6 \mathrm{HCl}(\mathrm{aq}) \longrightarrow 2 \mathrm{AlCl}_{3}(\mathrm{aq})+3 \mathrm{H}_{2}(\mathrm{~g}) \\
& 2 \mathrm{Al}(\mathrm{~s})+2 \mathrm{OH}^{-}(\mathrm{aq})+6 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow 2\left[\mathrm{Al}(\mathrm{OH})_{4}\right](\mathrm{aq})+3 \mathrm{H}_{2}(\mathrm{~g})
\end{aligned}
$$

Aluminium ion in aqueous solution is expected to be present as hexaaquaaluminium ion. However, hydrolysis of $\mathrm{Al}^{3+}$ produces $\left[\mathrm{Al}\left(\mathrm{OH}_{2}\right)_{5}(\mathrm{OH})\right]^{2+}($ pentaaquahydroxidoaluminium ion) and then produces $\left[\mathrm{Al}\left(\mathrm{OH}_{2}\right)_{4}(\mathrm{OH})_{2}\right]^{+}$(tetraaquadihydroxidoaluminium ion) as shown below.

$$
\begin{aligned}
& {\left[\mathrm{Al}\left(\mathrm{OH}_{2}\right)_{6}\right]^{3+}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons\left[\mathrm{Al}\left(\mathrm{OH}_{2}\right)_{5}(\mathrm{OH})\right]^{2+}(\mathrm{aq})+\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})} \\
& {\left[\mathrm{Al}\left(\mathrm{OH}_{2}\right)_{5}(\mathrm{OH})\right]^{2+}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons\left[\mathrm{Fl}\left(\mathrm{OH}_{2}\right)_{4}(\mathrm{OH})_{2}\right]^{+}(\mathrm{aq})+\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})}
\end{aligned}
$$

Addition of $\mathrm{OH}^{-}$ions to aluminum ions first produces a gelatinous precipitate of aluminum hydroxide. With excess $\mathrm{OH}^{-}$ions, the precipitated aluminum hydroxide is converted to tetrahydroxidoaluminate complex ion.

$$
\begin{aligned}
& \mathrm{Al}^{3+}(\mathrm{aq})+3 \mathrm{OH}^{-}(\mathrm{aq}) \longrightarrow \mathrm{Al}(\mathrm{OH})_{3}(\mathrm{~s})(\text { white gelatinous ppt) } \\
& \mathrm{Al}(\mathrm{OH})_{3}(\mathrm{~s})+\mathrm{OH}^{-}(\mathrm{aq}) \longrightarrow\left[\mathrm{Al}(\mathrm{OH})_{4}\right]^{-}(\mathrm{aq}) \text { or } \mathrm{AlO}_{2}^{-}(\mathrm{aq})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})
\end{aligned}
$$

Group 13 elements can have six electrons in their valence shell by forming three covalent bonds due to their $n s^{2} n p^{1}$ electron configuration. As a result, many of the Group 13 covalent compounds have an incomplete octet, so can act as Lewis acids to accept a pair of electrons from a donor. These compounds with incomplete octet are called electron deficient compounds. Both B and Al compounds with incomplete octet form dimers in the gaseous phase to satisfy the octet rule (Figure 4.2).

Figure 4.2 Structure of gaseous $\mathrm{Al}_{2} \mathrm{Cl}_{6}$

### 4.4 Group 14 elements

### 4.4.1 Group trends

Due to the formation of covalent bond network structure, the first three elements of group 14 have high melting points. Carbon is a nonmetal, whereas silicon and germanium are metalloids. Last two elements in the group, tin and lead are metals.

Carbon can be found in nature mainly in coal, crude oil, calcite $\left(\mathrm{CaCO}_{3}\right), \mathrm{CO}_{2}$ in air, magnesite $\left(\mathrm{MgCO}_{3}\right)$ and dolomite $\left(\mathrm{CaCO}_{3} \cdot \mathrm{MgCO}_{3}\right)$. Graphite, diamond and fullerenes are the allotropic forms of carbon. Fullerenes are recently found, and most well-known fullerene is $\mathrm{C}_{60}$, buckminsterfullerene (or bucky-ball). Carbon is the basis of life and the most important element in organic chemistry. Silicon and germanium are mainly used in the semiconductor industries. In addition, silicon is heavily used in inorganic polymer industry.

The properties of Group 14 elements are given in Table 4.7.
Table 4.7 Properties of Group 14 elements

|  | C | **Si | **Ge | **Sn | **Pb |
| :---: | :---: | :---: | :---: | :---: | :---: |

### 4.4.2 Diamond and graphite

Diamond and graphite are composed of homoatomic (same atoms) lattice structures. Diamond ( $s p^{3}$ hybridized carbon, tetrahedral) has a cubic crystalline structure. Graphite ( $s p^{2}$ hybridized carbon, trigonal planar) has stacked two-dimensional carbon layers. Carbon-carbon bonds in graphite are shorter than that of diamond (diamond 154 pm and graphite 141 pm ) due to the hybridization of carbon atoms. These two crystalline lattice structures are hard however diamond structure is the strongest lattice. Graphite is an electrical and a thermal conductor due to delocalizing $\pi$ electrons (Figure 4.3). Interactions between layers of carbon in graphite are weak and this makes graphite a good lubricant.
$\mathrm{sp}^{2}$ hybridization

Delocalized $\pi$ orbitals

Figure 4.3 Delocalizing $\pi$ bonds of graphite
Fullerenes are another series of carbon allotropes. In fullerenes, carbon atoms are connected in a spherical manner. Structures of graphite, diamond and fullerene $\left(\mathrm{C}_{60}\right)$ are shown in Figure 4.4.

Figure 4.4 Structures of (a) graphite, (b) diamond and (c) fullerene ( $\mathrm{C}_{60}$ )

### 4.4.3 Carbon monoxide and carbon dioxide

Carbon monoxide is a colourless, odourless, highly poisonous gas. Bond enthalpy of carbon monoxide is more than that of the $\mathrm{C}=\mathrm{O}$ double bond. In carbon monoxide, CO bond length is shorter than that of a typical $\mathrm{C}=\mathrm{O}$ double bond. This suggests that the bonding between C and O in carbon monoxide is not a typical $\mathrm{C}=\mathrm{O}$ double bond. It has a triple bond nature between the two atoms of C and O . The Lewis structure of CO is shown in Figure 4.5.

Figure 4.5 The Lewis structure of CO

Carbon monoxide is mostly used as a reducing agent in the production of iron. Also, CO plays an important role in many catalytic reactions as a ligand due to the lone pair of electrons on the C atom.

Carbon dioxide (Figure 4.6) solidifies due to London forces at low temperatures and/ or under high pressures. Solid $\mathrm{CO}_{2}$ (dry ice) sublimes to produce gaseous carbon dioxide under normal atmosperic conditions. It is commonly used as a freezing agent in the food industry and to produce artificial rain.

Figure 4.6 The Lewis structure of $\mathrm{CO}_{2}$

### 4.4.4 Oxoacid of carbon

Oxoacid of carbon is referred to as carbonic acid $\left(\mathrm{H}_{2} \mathrm{CO}_{3}\right)$ which is a weak acid. The bond structure of $\mathrm{H}_{2} \mathrm{CO}_{3}$ is given in Figure 4.7. Carbonic acid can be prepared by dissolving $\mathrm{CO}_{2}$ in water under pressure.

$$
\begin{aligned}
& \mathrm{CO}_{2}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{H}_{2} \mathrm{CO}_{3}(\mathrm{aq}) \\
& \mathrm{H}_{2} \mathrm{CO}_{3}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{HCO}_{3}^{-}(\mathrm{aq})+\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq}) \\
& \mathrm{HCO}_{3}^{-}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{CO}_{3}^{2-} \rightleftharpoons(\mathrm{aq})+\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})
\end{aligned}
$$

Figure 4.7 The bond structure of $\mathrm{H}_{2} \mathrm{CO}_{3}$
Hydrogen atom which is directly connected to oxygen atom can be released as a proton to the solution by exhibiting the acidic property of carbonic acid.

Carbon dioxide reacts with bases to produce carbonates showing its acidic property. In the presence of excess $\mathrm{CO}_{2}$ thus formed carbonates of Group 1 and 2 produce hydrogen carbonates.

$$
\begin{aligned}
& \mathrm{CO}_{2}(\mathrm{~g})+2 \mathrm{NaOH}(\mathrm{aq}) \longrightarrow \mathrm{Na}_{2} \mathrm{CO}_{3}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \\
& \mathrm{Na}_{2} \mathrm{CO}_{3}(\mathrm{aq})+\text { excess } \mathrm{CO}_{2}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow 2 \mathrm{NaHCO}_{3}(\mathrm{aq})
\end{aligned}
$$

### 4.5 Group 15 elements

### 4.5.1 Group trends

The first element, nitrogen of Group 15 shows different properties from the other elements in this group (Table 4.8). Metallic character of the Group 15 elements increases down the group. Nitrogen and phosphorous are nonmetals and show oxidation numbers -3 to +5 . Nitrogen can achieve +5 oxidation state with oxygen and fluorine. Dinitrogen, $\mathrm{N}_{2}$ is greatly stable (inert) under normal conditions due to strong triple bond ( $942 \mathrm{~kJ} \mathrm{~mol}^{-1}$ ). Except nitrogen, all the other elements exist as solids. The higher electronegativity, the smaller atomic radius and the absence of $d$ orbitals make nitrogen different from the other elements in the group.

Table 4.8 Properties of Group 15 elements

|  | N | **P | **As | **Sb | **Bi |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Ground state electronic configuration | $[\mathrm{He}] 2 \mathrm{~s}^{2} 2 \mathrm{p}^{3}$ | $[\mathrm{Ne}] 3 \mathrm{~s}^{2} 3 \mathrm{p}^{3}$ | $[\mathrm{Ar}] 3 \mathrm{~d}^{10} 4 \mathrm{~s}^{2} 4 \mathrm{p}^{3}$ | $[\mathrm{Kr}] 3 \mathrm{~d}^{10} 5 \mathrm{~s}^{2} 5 \mathrm{p}^{3}$ | $[\mathrm{Xe}] 4 \mathrm{f}^{14} 5 \mathrm{~d}^{10} 6 \mathrm{~s}^{2} 6 \mathrm{p}^{3}$ |

### 4.5.2 Chemistry of nitrogen

Nitrogen (boiling point is $195.8^{\circ} \mathrm{C}$ ) is slightly soluble in water under atmospheric pressure, but the solubility greatly increases with pressure. Nitrogen does not form allotropes. Dinitrogen shows only a few reactions and one of them is given below.

$$
3 \mathrm{Mg}(\mathrm{~s})+\mathrm{N}_{2}(\mathrm{~g}) \xrightarrow{\Delta} \mathrm{Mg}_{3} \mathrm{~N}_{2}(\mathrm{~s})
$$

Since nitrogen is an inert gas its chemical reactions occur under strong conditions. For an instance nitrogen gas reacts with oxygen in the presence of external energy from an elctrical spark. This reaction naturally occurs in lightening.

$$
\mathrm{N}_{2}(\mathrm{~g})+2 \mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{NO}_{2}(\mathrm{~g})
$$

Nitrogen shows oxidation states from -3 to +5 . Compounds with these oxidation states are shown in Table 4.9.

Table 4.9 Oxidation states of nitrogen

| Oxidation state | Compound | Formula | Bond structure |
| :---: | :---: | :---: | :---: |
| -3 | Ammonia | $\mathrm{NH}_{3}$ |  |
| -2 | Hydrazine | $\mathrm{N}_{2} \mathrm{H}_{4}$ |  |
| -1 | Hydroxylamine | $\mathrm{NH}_{2} \mathrm{OH}$ |  |
| 0 | Dinitrogen | $\mathrm{N}_{2}$ | $\mathrm{N} \equiv \mathrm{N}$ |
| +1 | Dinitrogen monoxide | $\mathrm{N}_{2} \mathrm{O}$ | $\mathrm{N}_{=}^{+}{ }^{+}=\mathrm{O} \leftrightarrow \mathrm{N} \equiv \mathrm{N}^{-} \mathrm{O}^{+}$ |
| +2 | Nitrogen monoxide | NO | $\dot{\mathrm{N}}=\mathrm{O}$ |
| +3 | Dinitrogen trioxide | $\mathrm{N}_{2} \mathrm{O}_{3}$ |  |
| +4 | Nitrogen dioxide | $\mathrm{NO}_{2}$ |  |
| +4 | Dinitrogen tetroxide | $\mathrm{N}_{2} \mathrm{O}_{4}$ |  |
| +5 | Nitric acid | $\mathrm{HNO}_{3}$ |  |
| +5 | Dinitrogen pentoxide |  |  |

### 4.5.3 Oxoacids of nitrogen

Nitrous acid which is unstable under normal atmospheric conditions is a weak acid. The bond structure of nitrous acid is given in Figure 4.8.

Figure 4.8 The bond structure of nitrous acid
Nitrous acid can undergo disproportionation to produce nitric acid and nitrogen monoxide which is a colourless gas.

$$
3 \mathrm{HNO}_{2}(\mathrm{aq}) \longrightarrow \mathrm{HNO}_{3}(\mathrm{aq})+2 \mathrm{NO}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

Futher reaction of nitrogen monoxide with oxygen forms nitrogen dioxide which is redish brown in colour.

$$
2 \mathrm{NO}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{NO}_{2}(\mathrm{~g})
$$

Nitric acid (Figure 4.9) is an oily and hazardous liquid. This acid is a strong oxidizing agent and can undergo vigorous chemical reactions.

Figure 4.9 The bond structure of nitric acid

Due to the light-induced decomposition, nitric acid produces oxygen and nitrogen dioxide.

$$
4 \mathrm{HNO}_{3}(\mathrm{aq}) \xrightarrow{h v} 4 \mathrm{NO}_{2}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

Due to this reason concentrated nitric acid is stored in brown colour glass bottles in laboratories.

## Oxidizing and reducing reactions of nitric acid

Dilute nitric acid reacts with metals to produce metal nitrate and hydrogen gas. In these reactions nitric acid acts as an oxidizing agent with respect to hydrogen. When magnesium and copper reacts with concentrated nitric acid it acts as an oxidizing agent with respect to nitrogen.

$$
\begin{aligned}
& \mathrm{Mg}(\mathrm{~s})+\text { dil. } 2 \mathrm{HNO}_{3}(\mathrm{aq}) \longrightarrow \mathrm{Mg}\left(\mathrm{NO}_{3}\right)_{2}(\mathrm{aq})+\mathrm{H}_{2}(\mathrm{~g}) \\
& \mathrm{Mg}(\mathrm{~s})+\text { conc. } 4 \mathrm{HNO}_{3}(\mathrm{l}) \longrightarrow \mathrm{Mg}\left(\mathrm{NO}_{3}\right)_{2}(\mathrm{aq})+2 \mathrm{NO}_{2}(\mathrm{~g})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \\
& 3 \mathrm{Cu}(\mathrm{~s})+\text { dil. } 8 \mathrm{HNO}_{3}(\mathrm{aq}) \longrightarrow 3 \mathrm{Cu}\left(\mathrm{NO}_{3}\right)_{2}(\mathrm{aq})+2 \mathrm{NO}(\mathrm{~g})+4 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \\
& \mathrm{Cu}(\mathrm{~s})+\text { conc. } 4 \mathrm{HNO}_{3}(\mathrm{l}) \longrightarrow \mathrm{Cu}\left(\mathrm{NO}_{3}\right)_{2}(\mathrm{aq})+2 \mathrm{NO}_{2}(\mathrm{~g})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})
\end{aligned}
$$

The reactions of conc. $\mathrm{HNO}_{3}$ acting as an oxidizing agent with non metals such as carbon and sulphur are given below.

$$
\begin{aligned}
& \mathrm{C}(\mathrm{~s})+\text { conc. } 4 \mathrm{HNO}_{3}(\mathrm{l}) \longrightarrow \mathrm{CO}_{2}(\mathrm{~g})+4 \mathrm{NO}_{2}(\mathrm{~g})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \\
& \mathrm{S}(\mathrm{~s})+\text { conc. } 6 \mathrm{HNO}_{3}(\mathrm{l}) \longrightarrow \mathrm{H}_{2} \mathrm{SO}_{4}(\mathrm{l})+6 \mathrm{NO}_{2}(\mathrm{~g})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})
\end{aligned}
$$

### 4.5.4 Ammonia and ammonium salts

Ammonia is a colourless gas with a strong characteristic smell. Ammonia is a basic gas which is readily soluble in water.

$$
\mathrm{NH}_{3}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{NH}_{4} \mathrm{OH}(\mathrm{aq})
$$

Ammonium hydroxide is a weak base and partially dissociates to produce ammonium ions and hydroxide ions.

$$
\mathrm{NH}_{4} \mathrm{OH}(\mathrm{aq}) \rightleftharpoons \mathrm{NH}_{4}^{+}(\mathrm{aq})+\mathrm{OH}^{-}(\mathrm{aq})
$$

Like any other base it reacts with dilute acids to produce aqueous salts.

$$
2 \mathrm{NH}_{4} \mathrm{OH}(\mathrm{aq})+\text { dil. } \mathrm{H}_{2} \mathrm{SO}_{4}(\mathrm{aq}) \longrightarrow\left(\mathrm{NH}_{4}\right)_{2} \mathrm{SO}_{4}(\mathrm{aq})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

Hydrolysis of the ammonium ion in aqueous solution produces the conjugate base, ammonia.

$$
\mathrm{NH}_{4}{ }^{+}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{NH}_{3}(\mathrm{aq})+\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{l})
$$

All amonium salts reacts with alkali to liberate amonia.

$$
\mathrm{NH}_{4} \mathrm{Cl}(\mathrm{aq})+\mathrm{NaOH}(\mathrm{aq}) \longrightarrow \mathrm{NaCl}(\mathrm{aq})+\mathrm{NH}_{3}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

## Reactions of ammonia

Ammonia acts as a reducing agent with chlorine, and the products vary with the amount of ammonia and chlorine used. In the presence of excess ammonia, chlorine produces nitrogen gas as one of the products. However, with excess chlorine, nitrogen trichloride is produced as one of the products, which is used for water disinfection.

$$
\text { excess ammonia, } 2 \mathrm{NH}_{3}(\mathrm{~g})+3 \mathrm{Cl}_{2}(\mathrm{~g}) \longrightarrow \mathrm{N}_{2}(\mathrm{~g})+6 \mathrm{HCl}(\mathrm{~g})
$$

The formed HCl further reacts with unreacted ammonia to form $\mathrm{NH}_{4} \mathrm{Cl}$. excess chlorine,

$$
3 \mathrm{Cl}_{2}(\mathrm{~g})+\mathrm{NH}_{3}(\mathrm{~g}) \longrightarrow 3 \mathrm{HCl}(\mathrm{~g})+\mathrm{NCl}_{3}(\mathrm{l})
$$

Nitrogen trichloride is a covalent chloride. It reacts with water to produce ammonia and hypochlorous acid. Due to the ability to produce hypochlorous acid, nitrogen trichloride is used as a water disinfecting agent.

$$
\mathrm{NCl}_{3}(\mathrm{l})+3 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow \mathrm{NH}_{3}(\mathrm{~g})+3 \mathrm{HOCl}(\mathrm{aq})
$$

Gaseous ammonia reacts with hydrogen chloride to produce a white smoke of solid ammonium chloride. This can be used as a confirmation test for ammonia.

$$
\mathrm{NH}_{3}(\mathrm{~g})+\mathrm{HCl}(\mathrm{~g}) \longrightarrow \mathrm{NH}_{4} \mathrm{Cl}(\mathrm{~s})
$$

Ammonia acts as a weak reducing agent with CuO and $\mathrm{Cl}_{2}$.

$$
\begin{aligned}
& 3 \mathrm{CuO}(\mathrm{~s})+2 \mathrm{NH}_{3}(\mathrm{~g}) \longrightarrow \mathrm{N}_{2}(\mathrm{~g})+3 \mathrm{Cu}(\mathrm{~s})+3 \mathrm{H}_{2} \mathrm{O}(\mathrm{~g}) \\
& 2 \mathrm{NH}_{3}(\mathrm{~g})+3 \mathrm{Cl}_{2}(\mathrm{~g}) \longrightarrow \mathrm{N}_{2}(\mathrm{~g})+6 \mathrm{HCl}(\mathrm{~g})
\end{aligned}
$$

Ammonia can act as an oxidizing agent as well as an acid with metals under dry condition.

$$
\begin{aligned}
& 2 \mathrm{Na}(\mathrm{~s})+2 \mathrm{NH}_{3}(\mathrm{l}) \longrightarrow 2 \mathrm{NaNH}_{2}(\mathrm{l})+\mathrm{H}_{2}(\mathrm{~g}) \\
& 3 \mathrm{Mg}(\mathrm{~s})+2 \mathrm{NH}_{3}(\mathrm{l}) \longrightarrow \mathrm{Mg}_{3} \mathrm{~N}_{2}(\mathrm{l})+3 \mathrm{H}_{2}(\mathrm{~g})
\end{aligned}
$$

## Thermal decomposition of ammonium salts

Some ammonium salts decompose upon heating to ammonium gas and to the acidic gas.

*Prodcts of this reaction can vary with conditions.
However, anions in some ammonium salts can oxidize the ammonium ion to produce many products upon heating.

$$
\begin{aligned}
& \mathrm{NH}_{4} \mathrm{NO}_{2}(\mathrm{~s}) \longrightarrow \mathrm{N}_{2}(\mathrm{~g})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{~g}) \\
& \mathrm{NH}_{4} \mathrm{NO}_{3}(\mathrm{~s}) \longrightarrow \mathrm{N}_{2} \mathrm{O}(\mathrm{~g})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{~g}) \\
& \left(\mathrm{NH}_{4}\right)_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}(\mathrm{~s}) \longrightarrow \mathrm{N}_{2}(\mathrm{~g})+\mathrm{Cr}_{2} \mathrm{O}_{3}(\mathrm{~s})+4 \mathrm{H}_{2} \mathrm{O}(\mathrm{~g})
\end{aligned}
$$

## Identification of ammonium salts

All ammonium salts produce ammonium gas with NaOH on warming. This gas produces white fumes of ammonium chloride when a glass rod moistened with concentrated hydrochloric acid.

$$
\begin{aligned}
& \mathrm{NH}_{4}^{+}(\mathrm{aq})+\mathrm{OH}^{-}(\mathrm{aq}) \longrightarrow \mathrm{NH}_{3}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \\
& \mathrm{NH}_{3}(\mathrm{~g})+\mathrm{HCl}(\mathrm{~g}) \longrightarrow \mathrm{NH}_{4} \mathrm{Cl}(\mathrm{~s}) \text { white fumes }
\end{aligned}
$$

## Reactions of nitrate

Reaction of nitrate with iron(II)/ conc. sulphuric acid can be used to identify nitrate ion. This test is known as brown ring test. The brown coloured $[\mathrm{Fe}(\mathrm{NO})]^{2+}$ ring formed in the test tube, confirms the presence of nitrate.
$2 \mathrm{NO}_{3}^{-}(\mathrm{aq})+4 \mathrm{H}_{2} \mathrm{SO}_{4}(\mathrm{l})+6 \mathrm{Fe}^{2+}(\mathrm{aq}) \longrightarrow 6 \mathrm{Fe}^{3+}(\mathrm{aq})+2 \mathrm{NO}(\mathrm{g})+4 \mathrm{SO}_{4}{ }^{2-}(\mathrm{aq})+4 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})$
$\mathrm{Fe}^{2+}(\mathrm{aq})+\mathrm{NO}(\mathrm{g}) \longrightarrow[\mathrm{Fe}(\mathrm{NO})]^{2+}(\mathrm{aq})$ brown colour
Nitrate reacts with $\mathrm{Al} / \mathrm{NaOH}$ to produce ammonia.

$$
3 \mathrm{NO}_{3}^{-}(\mathrm{aq})+8 \mathrm{Al}(\mathrm{~s})+5 \mathrm{OH}^{-}(\mathrm{aq})+18 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow 3 \mathrm{NH}_{3}(\mathrm{~g})+8\left[\mathrm{Al}(\mathrm{OH})_{4}\right]^{-}(\mathrm{aq})
$$

### 4.6 Group 16 elements

### 4.6.1 Group trends

First element, oxygen of Group 16 shows different properties to the other elements in the group. Metallic nature increases going down the group. However, none of the Group 16 elements behaves as true metals. Both oxygen and sulphur are non-metals and other elements in the group show metallic and nonmetallic properties. Only oxygen exists as a gas, and other elements in the group are solids. Except for oxygen, other elements in the group can form even-numbered oxidation states from +6 to -2 . Stability of +6 and -2 oxidation states decreases down the group whereas the stability of the +4 oxidation state increases.

Table 4.10 Properties of Group 16 elements

### 4.6.2 Hydrides of Group 16

Group 16 elements form simple hydrides with hydrogen. All of them are covalent hydrides. The variation of selected properties down the group of hydrides are shown in Table 4.11.

Table 4.11 Selected properties of Group 16 hydrides

|  | $\mathbf{H}_{2} \mathrm{O}$ | $\mathbf{H}_{2} \mathbf{S}$ | $\mathbf{H}_{2} \mathbf{S e}$ | $\mathbf{H}_{2} \mathbf{T e}$ |
| :--- | :--- | :--- | :--- | :--- |
| Melting point $/{ }^{\circ} \mathrm{C}$ | 0.0 | -85.6 | -65.7 | -51 |
| Boiling point $/{ }^{\circ} \mathrm{C}$ | 100.0 | -60.3 | -41.3 | -4 |
| Bond length $/ \mathrm{pm}$ | 96 | 134 | 146 | 169 |
| Bond angle $/{ }^{\circ}$ | 104.5 | 92.1 | 91 | 90 |

Due to the extensive hydrogen bonding, $\mathrm{H}_{2} \mathrm{O}$ shows abnormally high boiling and melting points than the other hydrides of the group. Water is the only non-poisonous hydride among all the other hydrides of the group.

The observed varation in bond length of covalent hydrides is due to the increase of size of the central atom. Therefore, bond length increases down the group.

The covalent bond angle decreases as you come down in the group due to the less repulsion of the bonding electrons as a result of electronegativity of the central atom
decreases down the group. In $\mathrm{H}_{2} \mathrm{~S}, \mathrm{H}_{2} \mathrm{Se}$ and $\mathrm{H}_{2} \mathrm{Te}$ the bond angles become close to $90^{\circ}$. This may also suggest that almost pure $p$ orbitals on selenium and tellurium especially are used for binding with hydrogen.

### 4.6.3 Oxygen

Oxygen has two allotropes, dioxygen $\left(\mathrm{O}_{2}\right)$ and trioxygen (ozone, $\mathrm{O}_{3}$ ). Dioxygen is a colourless and an odourless gas which is slightly soluble in water. Ozone has a pungent odour. Ozone has a bond angle of $111.5^{\circ}$. Structure of these two allotropes are shown below.

(a)

(b)

Figure 4.10 Structure of oxygen and ozone
Catalytic decomposition of potassium chlorate and hydrogen peroxide can be used to produce oxygen.

$$
\begin{aligned}
& 2 \mathrm{KClO}_{3}(\mathrm{~s}) \longrightarrow 2 \mathrm{KCl}(\mathrm{~s})+3 \mathrm{O}_{2}(\mathrm{~g}) \text {, heating in the presence of } \mathrm{MnO}_{2} \text { or } \mathrm{Pt} \\
& 2 \mathrm{H}_{2} \mathrm{O}_{2}(\mathrm{aq}) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})+\mathrm{O}_{2}(\mathrm{~g}) \text {, heating in the presence of } \mathrm{MnO}_{2}
\end{aligned}
$$

Metals react with dioxygen to produce metal oxides. Ozone is a powerful oxidizing agent stronger than dioxygen. Ozone is used to disinfect water in many developed countries to kill pathogens. Unlike chlorine, ozone does not produce any harmful byproducts in the disinfection process.

### 4.6.4 Sulphur

Sulphur can be classified as it is explained below.

Figure 4.11 Classification of sulphur
Unlike oxygen, sulphur forms single bonds with itself rather than double bonds. The most commonly occurring allotrope is rhombic sulphur which is referred to as $\alpha$-sulphur ( $\alpha$ -
$\mathrm{S}_{8}$ ). It has a crown shape with eight-membered ring that has a cyclic zigzag arrangement as shown below. When heated above $93^{\circ} \mathrm{C}, \alpha-\mathrm{S}_{8}$ changes its packing arrangement to the other commonly found form of monoclinic sulphur, $\beta$-sulphur ( $\beta$ - $S_{8}$ ). These two forms are allotropes of each other.

Figure 4.12 (a) crown form of $\mathrm{S}_{8}$ (b) Rhombic sulphur (c) Monoclinic sulphur
Crystalline form of rhombic and monoclinic sulphur consist of $\mathrm{S}_{8}$ rings in the shape of crown. These can be packed together in two different ways to form rhombic crystals and to form needle shaped monoclinic crystals as shown above. Below $95^{\circ} \mathrm{C}$ the rhombic form is the most stable allotropic form of sulphur.

Amorphous sulphur is an elastic form of sulphur which is obtained by pouring melted sulphur into water. Sudden cooling of molten sulphur with open chains converts liquid sulphur to amorphous sulphur with open chains. With time, amorphous sulphur converts to crystalline sulphur. The amorphous form of sulphur is malleable but it is unstable.

### 4.6.5 Oxygen containing compounds

Water and hydrogen peroxide
Structures of $\mathrm{H}_{2} \mathrm{O}$ and gaseous $\mathrm{H}_{2} \mathrm{O}_{2}$ are shown in the figures below.

(a)

(b)

Figure 4.13 Structures of (a) $\mathrm{H}_{2} \mathrm{O}$ and (b) $\mathrm{H}_{2} \mathrm{O}_{2}$

Water is the most widely used solvent. Water ionizes as follows. This is reffered to as self-ionization of water.

$$
2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})+\mathrm{OH}^{-}(\mathrm{aq})
$$

An amphiprotic molecule can either donate or accept a proton. Therefore, it can act as an acid or a base. Water is an amphiprotic compound since it has the ability to accept and release a proton. The amphoteric nature of water is shown below

$$
\begin{aligned}
& \mathrm{H}_{2} \mathrm{O}(\mathrm{l})+\mathrm{HCl}(\mathrm{aq}) \longrightarrow \mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})+\mathrm{Cl}^{-}(\mathrm{aq}) \\
& \mathrm{H}_{2} \mathrm{O}(\mathrm{l})+\mathrm{NH}_{3}(\mathrm{aq}) \rightleftharpoons \mathrm{NH}_{4}^{+}(\mathrm{aq})+\mathrm{OH}^{-}(\mathrm{aq})
\end{aligned}
$$

### 4.6.6 Hydrogen peroxide

Hydrogen peroxide $\left(\mathrm{H}_{2} \mathrm{O}_{2}\right)$ is a nonplanar molecule. The $\mathrm{H}_{2} \mathrm{O}_{2}$ molecule contains two OH groups which do not lie in the same plane and have a bent molecular shape with the bond angle in the gaseous phase for $\mathrm{H}-\mathrm{O}-\mathrm{O}$ as $94.8^{\circ}$. The structure shown in Figure 4.13 is the one that reduces with a minimum repulsion between the lone pairs found on the ' O ' atoms. The two H-O groups have a dihedral angle of $111.5^{\circ}$ between each other as indicated above in Figure 4.13.

Due to the extensive hydrogen bonding, $\mathrm{H}_{2} \mathrm{O}_{2}$ is a viscous liquid $\mathrm{H}_{2} \mathrm{O}_{2}$ can act as an oxidizing as well as a reducing agent. It oxidizes to oxygen and reduces to water.

Reducing half-reaction;

$$
\mathrm{H}_{2} \mathrm{O}_{2}(\mathrm{aq})+2 \mathrm{H}^{+}(\mathrm{aq})+2 \mathrm{e} \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

Oxidizing half-reaction;

$$
\mathrm{H}_{2} \mathrm{O}_{2}(\mathrm{aq}) \longrightarrow 2 \mathrm{H}^{+}(\mathrm{aq})+\mathrm{O}_{2}(\mathrm{~g})+2 \mathrm{e}
$$

Disproportionation;

$$
2 \mathrm{H}_{2} \mathrm{O}_{2}(\mathrm{aq}) \longrightarrow \mathrm{O}_{2}(\mathrm{~g})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

## Reactions of $\mathbf{H}_{\mathbf{2}} \mathrm{O}_{\mathbf{2}}$

$\mathrm{H}_{2} \mathrm{O}_{2}$ as an oxidizing agent;

$$
\begin{aligned}
& \mathrm{H}_{2} \mathrm{O}_{2}(\mathrm{aq})+2 \mathrm{H}^{+}(\mathrm{aq})+2 \mathrm{I}^{-}(\mathrm{aq}) \longrightarrow \mathrm{I}_{2}(\mathrm{aq})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \\
& \mathrm{H}_{2} \mathrm{O}_{2}(\mathrm{aq})+2 \mathrm{H}^{+}(\mathrm{aq})+2 \mathrm{Fe}^{2+}(\mathrm{aq}) \longrightarrow 2 \mathrm{Fe}^{3+}(\mathrm{aq})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})
\end{aligned}
$$

$\mathrm{H}_{2} \mathrm{O}_{2}$ as a reducing agent;

$$
\begin{aligned}
& 2 \mathrm{MnO}_{4}^{-}(\mathrm{aq})+5 \mathrm{H}_{2} \mathrm{O}_{2}(\mathrm{aq})+6 \mathrm{H}^{+}(\mathrm{aq}) \longrightarrow 2 \mathrm{Mn}^{2+}(\mathrm{aq})+5 \mathrm{O}_{2}(\mathrm{~g})+8 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \\
& \mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}(\mathrm{aq})+3 \mathrm{H}_{2} \mathrm{O}_{2}(\mathrm{aq})+8 \mathrm{H}^{+}(\mathrm{aq}) \longrightarrow 2 \mathrm{Cr}^{3+}(\mathrm{aq})+7 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})+3 \mathrm{O}_{2}(\mathrm{~g})
\end{aligned}
$$

### 4.6.7 Sulphur containing compounds

## Hydrogen sulphide

Hydrogen sulphide, $\mathrm{H}_{2} \mathrm{~S}$ is a colourless, toxic and acidic gas with the odour of "rotten eggs". $\mathrm{H}_{2} \mathrm{~S}$ can be produced by reacting metal sulphides with strong acids. It dissolves in water to produce weak acidic solutions.

## Reactions of hydrogen sulphide

$\mathrm{H}_{2} \mathrm{~S}$ as an acid with strong bases;

$$
\begin{aligned}
& \mathrm{NaOH}(\mathrm{aq})+\text { excess } \mathrm{H}_{2} \mathrm{~S}(\mathrm{~g}) \longrightarrow \mathrm{NaHS}(\mathrm{~s})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \\
& 2 \mathrm{NaOH}(\mathrm{aq})+\text { limited } \mathrm{H}_{2} \mathrm{~S}(\mathrm{~g}) \longrightarrow \mathrm{Na}_{2} \mathrm{~S}(\mathrm{~s})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})
\end{aligned}
$$

$\mathrm{H}_{2} \mathrm{~S}$ reacts with metals as an acid as well as an oxidizing agent;

$$
\begin{aligned}
& 2 \mathrm{Na}(\mathrm{~s})+\text { excess } 2 \mathrm{H}_{2} \mathrm{~S}(\mathrm{~g}) \longrightarrow 2 \mathrm{NaHS}^{2}(\mathrm{~s})+\mathrm{H}_{2}(\mathrm{~g}) \\
& 2 \mathrm{Na}(\mathrm{~s})+\text { limited } \mathrm{H}_{2} \mathrm{~S}(\mathrm{~g}) \longrightarrow \mathrm{Na}_{2} \mathrm{~S}(\mathrm{~s})+\mathrm{H}_{2}(\mathrm{~g}) \\
& \mathrm{Mg}(\mathrm{~s})+\mathrm{H}_{2} \mathrm{~S}(\mathrm{~g}) \longrightarrow \mathrm{MgS}(\mathrm{~s})+\mathrm{H}_{2}(\mathrm{~g})
\end{aligned}
$$

$\mathrm{H}_{2} \mathrm{~S}$ as a reducing agent;

$$
2 \mathrm{KMnO}_{4}(\mathrm{aq})+3 \mathrm{H}_{2} \mathrm{SO}_{4}(\mathrm{aq})+5 \mathrm{H}_{2} \mathrm{~S}(\mathrm{~g}) \longrightarrow \mathrm{K}_{2} \mathrm{SO}_{4}(\mathrm{aq})+5 \mathrm{~S}(\mathrm{~s})+2 \mathrm{MnSO}_{4}(\mathrm{aq})+8 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

$$
\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}(\mathrm{aq})+4 \mathrm{H}_{2} \mathrm{SO}_{4}(\mathrm{aq})+3 \mathrm{H}_{2} \mathrm{~S}(\mathrm{~g}) \longrightarrow \mathrm{K}_{2} \mathrm{SO}_{4}(\mathrm{aq})+\mathrm{Cr}_{2}\left(\mathrm{SO}_{4}\right)_{3}(\mathrm{aq})+3 \mathrm{~S}(\mathrm{~s})+7 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

$$
2 \mathrm{H}_{2} \mathrm{~S}(\mathrm{aq})+\mathrm{SO}_{2}(\mathrm{~g}) \longrightarrow 3 \mathrm{~S}(\mathrm{~s})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

## Sulphur dioxide

Sulphur dioxide is a colourless gas and soluble in water. Sulphur dioxide can act as an oxidizing and a reducing agent.

## Reactions of sulphur dioxide

As an oxidizing agent;

$$
\begin{aligned}
& 2 \mathrm{Mg}(\mathrm{~s})+\mathrm{SO}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{MgO}(\mathrm{~s})+\mathrm{S}(\mathrm{~s}) \\
& 3 \mathrm{Mg}(\mathrm{~s})+\mathrm{SO}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{MgO}(\mathrm{~s})+\mathrm{MgS}(\mathrm{~s})
\end{aligned}
$$

As a reducing agent;

$$
\begin{aligned}
& 5 \mathrm{SO}_{2}(\mathrm{~g})+2 \mathrm{KMnO}_{4}(\mathrm{aq})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow \mathrm{K}_{2} \mathrm{SO}_{4}(\mathrm{aq})+2 \mathrm{MnSO}_{4}(\mathrm{aq})+2 \mathrm{H}_{2} \mathrm{SO}_{4}(\mathrm{aq}) \\
& 3 \mathrm{SO}_{2}(\mathrm{~g})+\mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{SO}_{4}(\mathrm{aq}) \longrightarrow \mathrm{K}_{2} \mathrm{SO}_{4}(\mathrm{aq})+\mathrm{Cr}_{2}\left(\mathrm{SO}_{4}\right)_{3}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})
\end{aligned}
$$

$$
\mathrm{SO}_{2}(\mathrm{~g})+2 \mathrm{FeCl}_{3}(\mathrm{aq})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow \mathrm{H}_{2} \mathrm{SO}_{4}(\mathrm{aq})+2 \mathrm{FeCl}_{2}(\mathrm{aq})+2 \mathrm{HCl}(\mathrm{aq})
$$

### 4.6.8 Oxoacids of sulphur

Common oxidation numbers of sulphur are $-2,0,+2,+4$ and +6 .

## Sulphuric acid

Sulphuric acid is a strong diprotic acid. Sulphur trioxide reacts with water to produce sulphuric acid.

$$
\begin{aligned}
& \mathrm{SO}_{3}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow \mathrm{H}_{2} \mathrm{SO}_{4}(\mathrm{aq}) \\
& \mathrm{H}_{2} \mathrm{SO}_{4}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow \mathrm{HSO}_{4}^{-}(\mathrm{aq})+\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq}) \\
& \mathrm{HSO}_{4}^{-}-(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow \mathrm{SO}_{4}{ }^{2-}(\mathrm{aq})+\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})
\end{aligned}
$$

Concentrated sulphuric acid can act as a dehydrating agent.

$$
\begin{aligned}
& \mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}(\mathrm{~s}) \xrightarrow{\text { conc. } \mathrm{H}_{2} \mathrm{SO}_{4}} 6 \mathrm{C}(\mathrm{~s})+6 \mathrm{H}_{2} \mathrm{O}(\mathrm{~g}) \\
& \mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(\mathrm{l}) \xrightarrow{\text { conc. } \mathrm{H}_{2} \mathrm{SO}_{4}} \mathrm{C}_{2} \mathrm{H}_{4}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})
\end{aligned}
$$

Concentrated hot sulphuric acid can act as an oxidizing agent.
With metals,

$$
\begin{aligned}
2 \mathrm{H}_{2} \mathrm{SO}_{4}(\mathrm{l})+\mathrm{Mg}(\mathrm{~s}) & \longrightarrow \mathrm{SO}_{2}(\mathrm{~g})+\mathrm{MgSO}_{4}(\mathrm{aq})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \\
2 \mathrm{H}_{2} \mathrm{SO}_{4}(\mathrm{l})+\mathrm{Cu}(\mathrm{~s}) & \longrightarrow \mathrm{SO}_{2}(\mathrm{~g})+\mathrm{CuSO}_{4}(\mathrm{aq})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})
\end{aligned}
$$

With nonmetals,

$$
\begin{aligned}
& \mathrm{S}(\mathrm{~s})+2 \mathrm{H}_{2} \mathrm{SO}_{4}(\mathrm{l}) \longrightarrow 3 \mathrm{SO}_{2}(\mathrm{~g})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \\
& \mathrm{C}(\mathrm{~s})+2 \mathrm{H}_{2} \mathrm{SO}_{4}(\mathrm{l}) \longrightarrow \mathrm{CO}_{2}(\mathrm{~g})+2 \mathrm{SO}_{2}(\mathrm{~g})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})
\end{aligned}
$$

Dilute $\mathrm{H}_{2} \mathrm{SO}_{4}$ act as an acid.

$$
\begin{aligned}
& \mathrm{H}_{2} \mathrm{SO}_{4}(\mathrm{aq})+2 \mathrm{NaOH}(\mathrm{aq}) \longrightarrow \mathrm{Na}_{2} \mathrm{SO}_{4}(\mathrm{aq})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \\
& \mathrm{H}_{2} \mathrm{SO}_{4}(\mathrm{aq})+\mathrm{Mg}(\mathrm{~s}) \longrightarrow \mathrm{MgSO}_{4}(\mathrm{aq})+\mathrm{H}_{2}(\mathrm{~g})
\end{aligned}
$$

Dilute sulphuric acid is a strong acid which can protonate to give two $\mathrm{H}^{+}$ions to water as shown below.

$$
\mathrm{H}_{2} \mathrm{SO}_{4}(\mathrm{aq})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow \mathrm{SO}_{4}{ }^{2-}(\mathrm{aq})+2 \mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})
$$

Figure 4.14 Structure of sulphuric acid

## Sulphurous acid

Due to the air oxidation of sulphurous acid, it always contains a small amount of sulphuric acid. The reaction of gaseous sulphur dioxide and water produces sulphurous acid. The sulphurous acid reacts with dissolved oxygen in water to produce sulphric acid. Structure of the sulphurous acid is shown below. This acid is a weaker acid than sulphuric acid.

Figure 4.15 Structure of sufurous acid

## Thiosulphuric acid

Only the salts of thiosulphuric acid are stable and thiosulphate ion can oxidize as well as reduce to give sulphur and sulphur dioxide as its products. Thiosulphuric is a weak acid. In aqueous solutions, thiosulphuric acid can decompose to produce a mixture of sulphur containing products.

$$
\mathrm{H}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}(\mathrm{aq}) \longrightarrow \mathrm{S}(\mathrm{~s})+\mathrm{SO}_{2}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

Thiosulphate ion can act as a reducing agent.

$$
2 \mathrm{~S}_{2} \mathrm{O}_{3}{ }^{2-}(\mathrm{aq})+\mathrm{I}_{2}(\mathrm{aq}) \longrightarrow \mathrm{S}_{4} \mathrm{O}_{6}{ }^{2-}(\mathrm{aq})+2 \mathrm{I}^{-}(\mathrm{aq})
$$

Structures of thiosulphuric acid and thiosulphate ion are shown below. The oxidation state of the central sulphur atom is +4 where as the terminal sulphur is zero in both structures.

Figure 4.16 Thiosulphuric acid and thiosulphate ion

### 4.7 Group 17 elements

### 4.7.1 Group trends

Halogens are reactive and can only be found naturally as compounds. Fluorine is the most electronegative element and exhibits -1 and 0 oxidation states. The halogens other than fluorine form stable compounds corresponding to nearly all values of the oxidation numbers from -1 to +7 . However, compounds of bromine with the oxidation state of +7 are unstable. Due to the smaller atomic radius, fluorine can stabilize higher oxidation states of other elements.

Oxidizing ability of halogens decreases down the group. Fluorine is a powerful oxidizing agent. The reactivity of halegons decreases down the group. This can be explained by using the displacement reactions of halegons.

$$
\begin{aligned}
& \mathrm{Cl}_{2}(\mathrm{aq})+2 \mathrm{Br}^{-}(\mathrm{aq}) \longrightarrow 2 \mathrm{Cl}^{-}(\mathrm{aq})+\mathrm{Br}_{2}(\mathrm{aq}) \\
& \mathrm{Br}_{2}(\mathrm{aq})+2 \mathrm{I}^{-}(\mathrm{aq}) \longrightarrow 2 \mathrm{Br}^{-}(\mathrm{aq})+\mathrm{I}_{2}(\mathrm{aq})
\end{aligned}
$$

Fluorine and chlorine are gases with pale yellow and pale green colours respectively at room temperature. Bromine is a red-brown fumming liquid and iodine is a violet-black solid with lustrous effect.

The bond energy of $\mathrm{F}_{2}\left(155 \mathrm{~kJ} \mathrm{~mol}^{-1}\right)$ is less than that of $\mathrm{Cl}_{2}\left(240 \mathrm{~kJ} \mathrm{~mol}^{-1}\right)$ due to repulsion between the non-bonded electron pairs of fluorine atoms. This is a reason for the high reactivity of fluorine gas. Down the Group 17 bond energies show a gradual decrease $\left(\mathrm{Cl}_{2}=240 \mathrm{~kJ} \mathrm{~mol}^{-1}, \mathrm{Br}_{2}=190 \mathrm{~kJ} \mathrm{~mol}^{-1}\right.$ and $\left.\mathrm{I}_{2}=149 \mathrm{~kJ} \mathrm{~mol}^{-1}\right)$.

Table 4.12 Properties of Group 17 elements

### 4.7.2 Simple compounds of Group 17

## Hydrogen halides

Hydrogen halides are acidic in water. HF has the ability to produce extensive hydrogen bonding, however, HF is a gas (boiling point $20^{\circ} \mathrm{C}$ ) at room temperature and under atmospheric pressure.

## Acidic nature of hydrogen halides in aqueous solutions

For $\mathrm{HF} ; \mathrm{HF}(\mathrm{g})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq})$
For other hydrohen halides ( $\mathrm{HCl}, \mathrm{HBr}$ and HI );
$\mathrm{HX}(\mathrm{g})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow \mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})+\mathrm{X}^{-}(\mathrm{aq})$
HF is a weak acid whereas the other hydrogen halides are strong acids in the aqueous medium. HF has the high bond energy (strongest covalent bond), which makes it difficult to dissociate in water to produce $\mathrm{H}^{+}$ions readily. The acidic strength of hydrogen halides increases down the Group 17. This can be explained using the same fact mentioned above. Some selected properties of Group 17 hydrogen halides are shown in Table 4.13.

Table 4.13 Selected properties of group 17 hydrogen halides

|  | HF | HCl | HBr | HI |
| :--- | :--- | :--- | :--- | :--- |
| Melting point $/{ }^{\circ} \mathrm{C}$ | -84 | -114 | -89 | -51 |
| Boiling point $/{ }^{\circ} \mathrm{C}$ | 20 | -85 | -67 | -35 |
| Bond length $/ \mathrm{pm}$ | 92 | 127 | 141 | 161 |
| Bond dissociation energy/ $\mathrm{kJ} \mathrm{mol}^{-1}$ | 570 | 432 | 366 | 298 |

## Silver halides

Silver halides can be used to identify the halides (chloride, bromide, and iodide) using the colour of the precipitate. Few selected properties are shown below.

Table 4.14 Silver halides of Group 17 elements

| Silver halide | Colour | Solubility in ammonia |
| :--- | :--- | :--- |
| AgCl | White | Dissolves in dil. aqueous ammonia |
| AgBr | Pale yellow | Dissolves in conc. aqueous ammonia |
| AgI | Yellow | Insoluble in both dil. and conc. aqueous <br> ammonia |

## Oxides and oxoacids of chlorine

Chlorine forms several oxides and oxoanions with variable oxidation states. Some oxoanions are strong oxidizing agents. Selected oxides of chlorine are shown in Table 4.15 .

Table 4.15 Selected oxides and oxoanions of chlorine

| Oxidation state | Formula of oxide | Formula of oxoanion | Structure of oxoanion |
| :---: | :---: | :---: | :---: |
| +1 | $\mathrm{Cl}_{2} \mathrm{O}$ | $\mathrm{ClO}^{-}$ |  |
| +3 |  | $\mathrm{ClO}_{2}{ }^{-}$ |  |
| +5 |  | $\mathrm{ClO}_{3}{ }^{-}$ |  |
| +6 | $\mathrm{ClO}_{3}$ and $\mathrm{Cl}_{2} \mathrm{O}_{6}$ |  |  |
| +7 | $\mathrm{Cl}_{2} \mathrm{O}_{7}$ | $\mathrm{ClO}_{4}{ }^{-}$ |  |

Chlorine forms four types of oxoacids. The acidic strength increases with the increasing oxidation number of the chlorine atom. The stuctures and the oxidation states of oxoacids are given in the Table 4.16.

Table 4.16 Structures of oxoacids of chlorine

|  | HClO | $\mathrm{HClO}_{2}$ | $\mathrm{HClO}_{3}$ | $\mathrm{HClO}_{4}$ |
| :---: | :---: | :---: | :---: | :---: |
| Oxidation state | +1 | +3 | +5 | +7 |
| Structure |  |  |  |  |

Oxidizing power of oxoacids of chlorine changed as follows.
$\mathrm{HClO}>\mathrm{HClO}_{2}>\mathrm{HClO}_{3}>\mathrm{HClO}_{4}$
The oxidation state of chlorine in $\mathrm{HClO}, \mathrm{HClO}_{2}, \mathrm{HClO}_{3}, \mathrm{HClO}_{4}$ respectively are $+1,+3,+5$ and +7 . The higher the oxidation state the stronger the acid will be. Therefore the variation of acidic strength is $\mathrm{HClO}<\mathrm{HClO}_{2}<\mathrm{HClO}_{3}<\mathrm{HClO}_{4}$.

## Halides

Most covalent halides react vigorously with water. But $\mathrm{CCl}_{4}$ does not hydrolyze. Most fluorides and some other halides are inert.

Chlorides of group 14 and 15 elements react with less water as follows.

$$
\begin{aligned}
& \mathrm{SiCl}_{4}(\mathrm{l})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow 4 \mathrm{HCl}(\mathrm{aq})+\mathrm{SiO}_{2}(\mathrm{~s}) \\
& \mathrm{PCl}_{5}(\mathrm{l})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow \mathrm{POCl}_{3}(\mathrm{aq})+2 \mathrm{HCl}(\mathrm{aq})
\end{aligned}
$$

Chlorides of group 14 and 15 elements react excess water as follows.

$$
\begin{aligned}
& \mathrm{SiCl}_{4}(\mathrm{l})+3 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow 4 \mathrm{HCl}_{(\mathrm{aq})}+\mathrm{H}_{2} \mathrm{SiO}_{3}(\mathrm{aq}) \\
& \mathrm{NCl}_{3}(\mathrm{l})+3 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow \mathrm{NH}_{3}(\mathrm{aq})+3 \mathrm{HOCl}(\mathrm{aq}) \\
& \mathrm{PCl}_{3}(\mathrm{l})+3 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow \mathrm{H}_{3} \mathrm{PO}_{3}(\mathrm{aq})+3 \mathrm{HCl}(\mathrm{aq}) \\
& \mathrm{PCl}_{5}(\mathrm{l})+4 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow \mathrm{H}_{3} \mathrm{PO}_{4}(\mathrm{aq})+5 \mathrm{HCl}(\mathrm{aq}) \\
& \mathrm{AsCl}_{3}(\mathrm{~s})+3 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{H}_{3} \mathrm{AsO}_{3}(\mathrm{aq})+3 \mathrm{HCl}(\mathrm{aq}) \\
& \mathrm{SbCl}_{3}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{SbOCl}(\mathrm{~s})+2 \mathrm{HCl}(\mathrm{aq})
\end{aligned}
$$

$$
\mathrm{BiCl}_{3}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{BiOCl}(\mathrm{~s})+2 \mathrm{HCl}(\mathrm{aq})
$$

### 4.7.3 Reactions of chlorine

Chlorine is less reactive than fluorine. Chlorine gas is a strong oxidizing agent. Some reactions of chlorine act as a strong oxidizing agent are given below.

$$
\begin{aligned}
& 2 \mathrm{Cu}(\mathrm{~s})+\mathrm{Cl}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{CuCl}^{2}(\mathrm{~s}) \\
& 2 \mathrm{CuCl}(\mathrm{~s})+\mathrm{Cl}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{CuCl}_{2}(\mathrm{~s}) \\
& \mathrm{Fe}(\mathrm{~s})+\mathrm{Cl}_{2}(\mathrm{~g}) \longrightarrow \mathrm{FeCl}_{2}(\mathrm{~s}) \\
& 2 \mathrm{FeCl}_{2}(\mathrm{~s})+\mathrm{Cl}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{FeCl}_{3}(\mathrm{~s})
\end{aligned}
$$

$$
\text { excess ammonia, } 8 \mathrm{NH}_{3}(\mathrm{~g})+3 \mathrm{Cl}_{2}(\mathrm{~g}) \longrightarrow \mathrm{N}_{2}(\mathrm{~g})+6 \mathrm{HCl}(\mathrm{~g})
$$

$$
\text { excess chlorine, } 3 \mathrm{Cl}_{2}(\mathrm{~g})+\mathrm{NH}_{3}(\mathrm{~g}) \longrightarrow 3 \mathrm{HCl}(\mathrm{~g})+\mathrm{NCl}_{3}(\mathrm{l})
$$

## Disproportionation reactions of chlorine

Chlorine is simultaneously reduced and oxidized when it reacts with water and bases.

Reaction of chlorine with water;

$$
\mathrm{Cl}_{2}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow \mathrm{HOCl}(\mathrm{aq})+\mathrm{HCl}(\mathrm{aq})
$$

In this reaction, zero oxidation state of chlorine $\left(\mathrm{Cl}_{2}\right)$ oxidize to $+1(\mathrm{HOCl})$ and reduce to $-1\left(\mathrm{Cl}^{-}\right)$.

Reaction with sodium hydroxide;
With cold dilute sodium hydroxide

$$
\mathrm{Cl}_{2}(\mathrm{~g})+\text { cold and dil. } 2 \mathrm{NaOH}(\mathrm{aq}) \longrightarrow \mathrm{NaCl}(\mathrm{aq})+\mathrm{NaOCl}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

With hot concentrated/ hot dilute sodium hydroxide

$$
3 \mathrm{Cl}_{2}(\mathrm{~g})+\text { conc. } 6 \mathrm{NaOH}(\mathrm{aq}) \xrightarrow{\text { above } 80^{\circ} \mathrm{C}} 5 \mathrm{NaCl}(\mathrm{aq})+\mathrm{NaClO}_{3}(\mathrm{aq})+3 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

## Reactions of oxoanions

$\mathrm{ClO}^{-}$is stable at low temperatures and disproportionates at high temperature to produce $\mathrm{Cl}^{-}$and $\mathrm{ClO}_{3}{ }^{-}$. However, both $\mathrm{BrO}^{-}$and $\mathrm{IO}^{-}$are not stable even at low temperatures and undergo disproportionation.

## Disproportionation reactions of hypochlorite

Disproportionation of hypochlorite to produce chlorate and chloride can be written as;

$$
3 \mathrm{ClO}^{-} \rightleftharpoons \mathrm{ClO}_{3}^{-}+2 \mathrm{Cl}^{-}
$$

Under acidic conditions, HOCl is more stable than $\mathrm{ClO}^{-}$, which makes disproportionation predominant under basic conditions.

### 4.8 Group 18 elements

### 4.8.1 Group trends

All group 18 elements are unreactive monoatomic gasses. Only Xe forms a significant range of compounds. All group 18 elements have positive electron gain enthalpy because an incoming electron needs to occupy an orbital belonging to a new shell.

Table 4.17 Properties of Group 18 elements

|  | $\mathbf{H e}$ | $\mathbf{N e}$ | $\mathbf{A r}$ | $\mathbf{K r}$ | $\mathbf{X e}$ |
| :--- | ---: | ---: | ---: | ---: | ---: |
| Ground state <br> electronic <br> configuration | $1 s^{2}$ | $[\mathrm{He}] 2 s^{2} 2 p^{6}$ | $[\mathrm{Ne}] 3 s^{2} 3 p^{6}$ | $[\mathrm{Ar}] 3 d^{10} 4 s^{2} 4 p^{6}$ | $[\mathrm{Xe}] 4 d^{105 s^{2} 5 p^{6}}$ |
| Atomic radius/ pm | 99 | 160 | 192 | 197 | 240 |
| $1^{\text {st }} \mathrm{lionization} \mathrm{energy/}$ <br> $\mathrm{~kJ} \mathrm{~mol}^{-1}$ | 2373 | 2080 | 1520 | 1350 | 1170 |
| Electron gain <br> enthalpy/ $\mathrm{kJ} \mathrm{mol}^{-1}$ | 48.2 | 115.8 | 96.5 | 96.5 | 77.2 |

### 4.8.2 Simple compounds of group 18 elements

Compounds of xenon have oxidation numbers of $+2,+4,+6$ and +8 . Xenon reacts directly with fluorine. Some Xe compounds are shown in Table 4.18.

Table 4.18 Some selected compounds of Xe

### 4.9 Periodic trends shown by $s$ and $\boldsymbol{p}$ block elements

### 4.9.1 The valence electron configuration

The valance electron configuration of an element can be predicted from their position in the periodic table.

| Group number | 1 | 2 | 13 | 14 | 15 | 16 | 17 | 18 |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Valance shell <br> electron <br> configuration | $\mathrm{n} s^{1}$ | $\mathrm{n} s^{2}$ | $\mathrm{n} s^{2} \mathrm{n} p^{1}$ | $\mathrm{n} s^{2} \mathrm{n} p^{2}$ | $\mathrm{n} s^{2} \mathrm{n} p^{3}$ | $\mathrm{n} s^{2} \mathrm{n} p^{4}$ | $\mathrm{n} s^{2} \mathrm{n} p^{5}$ | $\mathrm{n} s^{2} \mathrm{n} p^{6}$ |

### 4.9.2 Metallic character

Metals have lower ionization energies compared to the other elements. Hence, metals can easily release electrons to produce cations. The atomic radii increase and ionization energy decreases when going down a group. Therefore, the metallic nature increases down the group. Also, across a period, atomic radii decrease and ionization energy increases. Therefore, the metallic nature decreases.

The third period shows a gradual increase in melting point and then a decrease across the period. Most abundant elemental form, type of bonding between similar atoms and the melting point of the third period elements are shown below.

Table 4.19 Most abundant elemental form, type of bonding between similar atoms and the melting point of the third period elements

|  | Na | Mg | Al | Si | $\mathrm{P}_{4}$ | $\mathrm{~S}_{8}$ | $\mathrm{Cl}_{2}$ | Ar |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Melting point $/{ }^{\circ} \mathrm{C}$ | 98 | 649 | 660 | 1420 | 44 | 119 | -101 | -189 |
| Bonding type | M | M | M | NC | C | C | C | - |

## Acid, base and amphoteric nature of oxides

Across the third period variation of type of bonding in oxides in which the elements are at their highest oxidation number are given below.

Table 4.20 Comparison of the third period oxides

|  | $\mathrm{Na}_{2} \mathrm{O}(\mathrm{s})$ | $\mathrm{MgO}(\mathrm{s})$ | $\mathrm{Al}_{2} \mathrm{O}_{3}(\mathrm{~s})$ | $\mathrm{SiO}_{2}(\mathrm{~s})$ | $\mathrm{P}_{4} \mathrm{O}_{10}(\mathrm{~s})$ | $\mathrm{SO}_{3}(\mathrm{~g})$ | $\mathrm{Cl}_{2} \mathrm{O}_{7}(\mathrm{l})$ |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Oxidation <br> number | +1 | +2 | +3 | +4 | +5 | +6 | +7 |
| Bonding <br> type | I | I | I | NC | C | C | C |
| Nature | Strongly | B | Am | Very <br> weakly <br> A | Weakly | A | Atrong |
| B |  |  |  |  |  |  |  |

Oxides with the highest oxidation number are considered to compare the chemical nature.
The nature from strong basic on the left to strong acidic to the right can be seen.
Amphoteric nature can be seen in the middle of the series.

### 4.9.3 Reactions of third period oxides with water, acids and bases

Oxides of sodium and magnesium react with water to produce hydroxides.

$$
\begin{aligned}
& \mathrm{Na}_{2} \mathrm{O}(\mathrm{~s})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow \mathrm{NaOH}(\mathrm{aq}) \\
& \mathrm{MgO}(\mathrm{~s})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow \mathrm{Mg}(\mathrm{OH})_{2} \\
& 156
\end{aligned}
$$

As these two oxides are basic, they react with acids to produce salt and water.

$$
\begin{aligned}
& \mathrm{Na}_{2} \mathrm{O}(\mathrm{~s})+2 \mathrm{HCl}(\mathrm{aq}) \longrightarrow 2 \mathrm{NaCl}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \\
& \mathrm{MgO}(\mathrm{~s})+2 \mathrm{HCl}(\mathrm{aq}) \longrightarrow \mathrm{MgCl}_{2}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})
\end{aligned}
$$

Aluminum oxide is amphoteric and it reacts with acids as well as with bases to produce salts.

$$
\begin{aligned}
& \mathrm{Al}_{2} \mathrm{O}_{3}(\mathrm{~s})+6 \mathrm{HCl}(\mathrm{aq}) \longrightarrow 2 \mathrm{AlCl}_{3}(\mathrm{aq})+3 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \\
& \mathrm{Al}_{2} \mathrm{O}_{3}(\mathrm{~s})+2 \mathrm{NaOH}(\mathrm{aq})+3 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow 2 \mathrm{Na}\left[\mathrm{Al}(\mathrm{OH})_{4}\right](\mathrm{aq})
\end{aligned}
$$

$\mathrm{SiO}_{2}$ is weakly acidic and reacts with strong bases. Also, $\mathrm{SiO}_{2}$ shows no reaction with water.

$$
\mathrm{SiO}_{2}(\mathrm{~s})+2 \mathrm{NaOH}(\mathrm{aq}) \longrightarrow \mathrm{Na}_{2} \mathrm{SiO}_{3}(\mathrm{aq})
$$

$\mathrm{P}_{4} \mathrm{O}_{10}, \mathrm{SO}_{3}$, and $\mathrm{Cl}_{2} \mathrm{O}_{7}$ are acidic and produce acids when dissolved in water. Those reactions are shown below.

$$
\begin{aligned}
& \mathrm{P}_{4} \mathrm{O}_{10}(\mathrm{~s})+6 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow 4 \mathrm{H}_{3} \mathrm{PO}_{4}(\mathrm{aq}) \\
& \mathrm{SO}_{3}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow \mathrm{H}_{2} \mathrm{SO}_{4}(\mathrm{aq}) \\
& \mathrm{Cl}_{2} \mathrm{O}_{7}(\mathrm{l})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow 2 \mathrm{HClO}_{4}(\mathrm{aq})
\end{aligned}
$$

These oxides also react with bases to produce salts and water.

$$
\begin{aligned}
& \mathrm{P}_{4} \mathrm{O}_{10}(\mathrm{~s})+12 \mathrm{NaOH}(\mathrm{aq}) \longrightarrow 4 \mathrm{Na}_{3} \mathrm{PO}_{4}(\mathrm{aq})+6 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \\
& \mathrm{SO}_{3}(\mathrm{~g})+2 \mathrm{NaOH}(\mathrm{aq}) \longrightarrow \mathrm{Na}_{2} \mathrm{SO}_{4}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \\
& \mathrm{Cl}_{2} \mathrm{O}_{7}(\mathrm{l})+2 \mathrm{NaOH} \longrightarrow 2 \mathrm{NaClO}_{4}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})
\end{aligned}
$$

4.9.4 Acid, base and amphoteric nature of hydroxides and hydrides

Hydroxides of the third period show a trend similar to oxides of the same period. The following table shows a comparison of the third period hydroxides.

Table 4.21 Comparison of the third period hydroxides

|  | NaOH | $\mathrm{Mg}(\mathrm{OH})_{2}$ | $\mathrm{Al}(\mathrm{OH})_{3}$ | $\mathrm{Si}(\mathrm{OH})_{4}$ | $\mathrm{P}(\mathrm{OH})_{5}$ | $\mathrm{S}(\mathrm{OH})_{6}$ | $\mathrm{Cl}(\mathrm{OH})_{7}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Stable form |  |  |  | $\mathrm{H}_{2} \mathrm{SiO}_{3}$ | $\mathrm{H}_{3} \mathrm{PO}_{4}$ | $\mathrm{H}_{2} \mathrm{SO}_{4}$ | $\mathrm{HClO}_{4}$ |
| Oxidation number | +1 | +2 | +3 | +4 | +5 | +6 | +7 |
| Bonding type | I | I | C | C | C | C | C |
| Nature | Strongly B | B | Am | Very weakly A | Weakly A | Strongly A | $\begin{aligned} & \text { Very } \\ & \text { strongly } \\ & \text { A } \\ & \hline \end{aligned}$ |
| Ionic - I, Network covalent - NC, Covalent - C |  |  |  |  |  |  |  |

Nature of hydrides of third period varies from strong bases to strong acids across the period. Amphoteric nature can be seen in the middle of the series.

Table 4.22 Comparison of the third period hydrides

|  | $\mathrm{NaH}(\mathrm{s})$ | $\mathrm{MgH}_{2}(\mathrm{~s})$ | $\left(\mathrm{AlH}_{3}\right)_{\mathrm{x}}(\mathrm{s})$ | $\mathrm{SiH}_{4}(\mathrm{~g})$ | $\mathrm{PH}_{3}(\mathrm{~g})$ | $\mathrm{H}_{2} \mathrm{~S}(\mathrm{~g})$ | $\mathrm{HCl}(\mathrm{g})$ |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Oxidation <br> number | +1 | +2 | +3 | -4 | -3 | -2 | -1 |
| Nature of <br> the aqueous <br> solution | Strongly | Weakly <br> B | Am | Very <br> weakly | N | Weakly A | Very <br> strongly A |
| Bonding <br> type | I | I | NC | C | C | C | C |

Hydrides of sodium and magnesium react with water to produce basic solutions.

$$
\begin{aligned}
& \mathrm{NaH}(\mathrm{~s})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow \mathrm{NaOH}(\mathrm{aq})+\mathrm{H}_{2}(\mathrm{~g}) \\
& \mathrm{MgH}_{2}(\mathrm{~s})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow \mathrm{Mg}(\mathrm{OH})_{2}(\mathrm{~s})+2 \mathrm{H}_{2}(\mathrm{~g}) \\
& \mathrm{AlH}_{3}(\mathrm{~s})+3 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow \mathrm{Al}(\mathrm{OH})_{3}(\mathrm{~s})+3 \mathrm{H}_{2}(\mathrm{~g})
\end{aligned}
$$

$\mathrm{PH}_{3}$ is weakly soluble in water and produces a neutral solution. $\mathrm{H}_{2} \mathrm{~S}$ and HCl are acidic and aqueous solutions are also acidic.

$$
\begin{aligned}
& \mathrm{H}_{2} \mathrm{~S}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow \mathrm{HS}^{-}(\mathrm{aq})+\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq}) \\
& \mathrm{HCl}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow \mathrm{Cl}^{-}(\mathrm{aq})+\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})
\end{aligned}
$$

### 4.9.5 Nature of the halides across the third period

As the electronegativity of elements increases across the period from left to right, the ability of hydrolyzation of chlorides increases accordingly. Corresponding reactions are given below. Chlorides of $s$ block elements in the third period are ionic and the $p$ block elements are covalent.

Table 4.23 Comparison of the third period chlorides

|  | $\mathrm{NaCl}(\mathrm{s})$ | $\mathrm{MgCl}_{2}(\mathrm{~s})$ | $\mathrm{AlCl}_{3}(\mathrm{~s})$ | $\mathrm{SiCl}_{4}(\mathrm{l})$ | $\mathrm{PCl}_{5}(\mathrm{~g})$ | $\mathrm{SCl}_{2}(\mathrm{~g})$ |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Oxidation number | +1 | +2 | +3 | +4 | +5 | +2 |
| Bonding type | I | I | C | C | C | C |
| Nature of the aqueous <br> solution | N | Very <br> weakly <br> A | A | A | A | A |
|  |  | A |  |  |  |  |
| Basic - B, Amphoteric - Am, Acidic - A, Neutral -N |  |  |  |  |  |  |

Reactions with water of third period covalent chlorides are,

$$
\begin{aligned}
& \mathrm{AlCl}_{3}(\mathrm{~s})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow\left[\mathrm{Al}^{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{5} \mathrm{OH}\right]^{2+}(\mathrm{aq})+\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq}) \\
& \mathrm{SiCl}_{4}(\mathrm{l})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow \mathrm{SiO}_{2}(\mathrm{~s})+4 \mathrm{HCl}(\mathrm{aq}) \\
& \mathrm{PCl}_{5}(\mathrm{~g})+4 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow \mathrm{H}_{3} \mathrm{PO}_{4}(\mathrm{aq})+5 \mathrm{HCl}(\mathrm{aq}) \\
& 2 \mathrm{SCl}_{2}(\mathrm{~g})+3 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow \mathrm{H}_{2} \mathrm{SO}_{3}(\mathrm{aq})+\mathrm{S}(\mathrm{~s})+4 \mathrm{HCl}(\mathrm{aq})
\end{aligned}
$$

Group 15 can be used to understand the variation of properties down the group. Down a group the ionization energy decreases, and the metallic nature increases. Use the information given for the Group 15 and correlate the variation in ionization energies with the increase of metallic properties down the group. Both N and P are nonmetals and produce acidic oxides. However, As and Sb oxides are amphoteric and bismuth oxide is basic.

Reactions with water of group 15 halides are given in the respective section under the halides of group 17.

## d Block Elements

Elements in Groups 3 to 12 are collectively classified as $d$ block elements. In $d$ block elements the last electron gets filled into a $d$ orbital. These elements can be categorised into two categories namely transition and non-transition.

### 4.10 Transition elements

$d$ block elements contain incompletely filed $d$ subshell at elemental state or with the ability to form at least one stable ion with incompletely filled $d$ subshell are called transition elements. Therefore, $d$ block elements producing ions only with $d^{10}$ configurations are considered as non-transition elements.
e.g.: Electronic configurations of $\mathrm{Zn}:[\mathrm{Ar}] 3 d^{10} 4 s^{2}$

Electronic configurations of $\mathrm{Zn}^{2+}:[\mathrm{Ar}] 3 d^{10} 4 s^{0}$
Electronic configuration of $\mathrm{Sc}:[\mathrm{Ar}] 3 d^{1} 4 s^{2}$
Electronic configuration of $\mathrm{Sc}^{3+}:[\mathrm{Ar}] 3 d^{0} 4 s^{0}$
Both Zn and Sc are $d$ block elements (last electron is filled to a $3 d$ orbital). However, Zn is considered as a non-transition element due to the absence of a partially filed $d$ subshell at the elemental stage and $\mathrm{Zn}^{2+}$ ion. Sc can be considered as a transition element since Sc contains partially filed d subshell at the elemental stage.

Table 4.24 Comparison of the properties of $d$ block elements in fourth period

| Group | $\mathbf{3}$ | $\mathbf{4}$ | $\mathbf{5}$ | $\mathbf{6}$ | $\mathbf{7}$ | $\mathbf{8}$ | $\mathbf{9}$ | $\mathbf{1 0}$ | $\mathbf{1 1}$ | $\mathbf{1 2}$ |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Element | Sc | Ti | V | Cr | Mn | Fe | Co | Ni | Cu | Zn |
| Pauling <br> electronegativity | 1.3 | 1.5 | 1.6 | 1.6 | 1.5 | 1.9 | 1.9 | 1.9 | 1.9 | 1.6 |
| Atomic <br> radius/pm | 162 | 147 | 134 | 128 | 127 | 126 | 125 | 125 | 128 | 137 |
| Covalent <br> radius/pm | 144 | 132 | 122 | 118 | 117 | 117 | 116 | 115 | 117 | 125 |
| Ionic radius $\left(\mathrm{M}^{2+}\right) /$ <br> pm | - | 100 | 93 | 87 | 81 | 75 | 79 | 83 | 87 | 88 |

Transition metal ions have less variation in atomic radii across a period than that of the main group elements. Across the period of the transition metals shown in Table 4.23, the atomic radii decrease slightly and then increase. Across the period, to each $d$ electron added nuclear charge is also increased by one. The decrease of the atomic radii at the middle of the period (from Sc to Ni ) occurs due to the predominance of attraction power of nuclear charge increase than the repulsion among the electrons. However, at the end of the period $(\mathrm{Cu}$ and Zn$)$, radii of the atoms increase due to greater repulsion among electrons as electrons are paired in $d$ orbitals.

### 4.10.1 Occurrence

Elements on the left of the $3 d$ series (fourth period $d$ block elements) exit commonly in the nature as metal oxides and cations combined with anions.

Few examples are shown below.
Table 4.25 Occurrence of some fourth period $d$ block elements

| Element | Example |
| :--- | :--- |
| Ti | $\mathrm{FeTiO}_{3}$ (Ilmenite) and $\mathrm{TiO}_{2}$ (Rutile) |
| Fe | $\mathrm{Fe}_{2} \mathrm{O}_{3}$ (Haematite), $\mathrm{Fe}_{3} \mathrm{O}_{4}$ (Magnetite) and $\mathrm{FeCO}_{3}$ (Siderite) |
| Cu | $\mathrm{CuFeS}_{2}$ (Copper Pyrite) |

### 4.10.2 Properties of fourth period $\boldsymbol{d}$ block elements

 Oxidation states and ionization energiesExcept Sc and Zn in the fourth period $d$ block elements, others can form stable cations with multiple oxidation states. The multiplicity of the oxidation state is due to the varying number of $d$ electrons participate in bonding. Both $\mathrm{Zn}(+2)$ and $\mathrm{Sc}(+3)$ only produce ions with a single oxidation state, and these ions do not contain partially filled $d$ orbitals. Electron configuration and the oxidation states of $d$ block elements are shown in Table 4.26. Sc forms only $\mathrm{Sc}^{3+}$ ions. Except in $\mathrm{Sc},+2$ oxidation number can be seen in all the other elements since electrons in $4 s$ orbital get removed due to ionization before electrons in $3 d$ orbitals. Reason for this is that the $4 s$ orbital with two electrons in the outermost shell experiences a lesser effective nuclear charge than that of electrons in the $3 d$ orbital.

As a result of the $3 d^{10} 4 s^{1}$ configuration, Cu can form +1 oxidation number commonly. However, $\mathrm{Cr}^{+}$is extremely rare and unstable even though Cr has $3 d^{5} 4 s^{1}$ configuration.

The highest possible oxidation number that a d block element can show is the sum of $4 s$ and $3 d$ electrons. Transition metals are also capable of producing variable oxidation states similar to $p$ block elements and show the ability to interconvert among their oxidation states. Therefore, they can act as oxidizing as well as reducing agents.

First five elements achieve the maximum possible oxidation state by losing all $4 s$ and $3 d$ electrons. With the filling of more $3 d$ electrons, towards the right end of the period, the $3 d$ orbitals become greater in energy as the nuclear charge of the atom increases. This makes $d$ electrons are harder to remove. The most common oxidation state for these elements is +2 due to the loss of $4 s$ electrons.

## Reactivity

$d$ block elements do not react with the water while $s$ block elements react with water vigorously. The $4 s$ electrons of the $d$ block elements are tightly bound to the nucleus due
to the higher nuclear charge than that of the $s$ block elements．First ionization energy of $d$ block elements lies between the values of those of $s$ and $p$ block elements．

Table 4．26 Electronic configuration and oxidation states of $d$ block elements

| Element | Ground state configuration |  |  | Oxidation states |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | $3 d$ |  | $4 s$ |  |
| Sc | $[\mathrm{Ar}] 3 \mathrm{~d}^{1} 4 \mathrm{~s}^{2}$ | $\uparrow$ |  | 个ı | ＋3 |
| Ti | ［Ar］ $3 \mathrm{~d}^{2} 4 \mathrm{~s}^{2}$ | $\uparrow \uparrow$ |  | $\uparrow \downarrow$ | （＋2），＋3，＋4 |
| V | $[\mathrm{Ar}] 3 \mathrm{~d}^{3} 4 \mathrm{~s}^{2}$ | $\uparrow \uparrow$ | $\uparrow$ | Tı | （＋2），（＋3），＋4，＋5 |
| Cr | ［Ar］ $3 \mathrm{~d}^{5} 4 \mathrm{~s}^{1}$ | $\bigcirc \uparrow \uparrow$ | $\uparrow \uparrow \uparrow$ | $\uparrow$ | ＋2，＋3，（＋4），（＋5），＋6 |
| Mn | $[\mathrm{Ar}] 3 \mathrm{~d}^{5} 4 \mathrm{~s}^{2}$ | T $\uparrow$ | $\uparrow \uparrow \uparrow$ | 1ı | ＋2，＋3，＋4，（＋5），（＋6），＋7 |
| Fe | $[\mathrm{Ar}] 3 \mathrm{~d}^{6} 4 \mathrm{~s}^{2}$ | 个८ $\downarrow$ | $\uparrow \uparrow \uparrow$ | 个ı | ＋2，＋3，（＋4），（＋5），（＋6） |
| Co | $[\mathrm{Ar}] 3 \mathrm{~d}^{7} 4 \mathrm{~s}^{2}$ | T८ $\downarrow$ T | $\uparrow$ 1 $\uparrow$ ¢ | 1． | ＋2，＋3，（＋4） |
| Ni | ［ Ar$] 3 \mathrm{~d}^{8} 4 \mathrm{~s}^{2}$ | T¢ $\downarrow$ ¢ $\downarrow$ | $\uparrow \downarrow \uparrow \uparrow$ | Tı | ＋2，（＋3），（＋4） |
| Cu | ［Ar］${ }^{\text {d }}{ }^{10} 4 \mathrm{~s}^{1}$ | T¢ $\downarrow$ ¢ $\downarrow$ | $\uparrow \downarrow \uparrow \downarrow \uparrow \downarrow$ | $\uparrow$ | ＋1，＋2，（＋3），（＋4） |
| Zn | ［Ar］ $3 \mathrm{~d}^{10} 4 \mathrm{~s}^{2}$ | $\uparrow \downarrow \uparrow \downarrow$ | $\uparrow \downarrow \uparrow \downarrow \uparrow \downarrow$ | $\uparrow \downarrow$ | ＋2 |

＊Less common states are shown in brackets．

Ionization energies of fourth period $d$ block elements are higher than that of the $s$ block elements in the same period．The first ionization energies of $d$ block elements are increase slightly across the period when move from left to the right of the period．Variation of the first ionization energy across the $d$ block is less than that of $s$ and $p$ block elements． Increase in the nuclear charge across the fourth period $d$ block elements expect to be increase the first ionization energies due to the greater attraction towards the $4 s$ electrons． However，in all $d$ block elements，extra electrons are inserted in to the $3 d$ orbital moving from left to right across the period，and these $d$ electrons shield the 4 s electrons from the inward attraction of the nucleus．Because of these two counter effects，the ionization energy of $d$ block elements increases slightly across the period．Successive ionization energies of the fourth period $d$ block elements are shown in the table given below．

Table 4.27 Successive ionization energies of fourth period $d$ block metals, K and $\mathrm{Ca} . * *$

| Element | $1^{\text {st }}$ ionization energy/ $\mathrm{kJ} \mathrm{mol}^{-1}$ | $2^{\text {nd }}$ ionization energy/ $\mathrm{kJ} \mathrm{mol}^{-1}$ | $3^{\text {rd }}$ ionization energy/ $\mathrm{kJ} \mathrm{mol}^{-1}$ |
| :---: | :---: | :---: | :---: |
| K | 418 | 3052 |  |
| Ca | 589 | 1145 | 4912 |
| Sc | 631 | 1235 | 2389 |
| Ti | 658 | 1310 | 2652 |
| V | 650 | 1414 | 2828 |
| Cr | 653 | 1496 | 2987 |
| Mn | 717 | 1509 | 3248 |
| Fe | 759 | 1561 | 2957 |
| Co | 758 | 1646 | 3232 |
| Ni | 737 | 1753 | 3393 |
| Cu | 746 | 1958 | 3554 |
| Zn | 906 | 1733 | 3833 |

** For K, only first and second ionization energies are given to understand the energy increase due to removal of an electron from an inner orbital.

First ionization energies of $d$ block elements are higher than those of $s$ block elements in the same period. This explains the less reactivity of $d$ block elements than the $s$ block elements.

All $d$ block elements are metals because $4 s$ electrons in $d$ block elements can be released easily to form cations. Metallic character of the $d$ block elements increases down the group.

All $d$ block elements in the fourth period are solids with high melting and boiling points. Melting and boiling points of $d$ block elements are extremely high as compared to those of $s$ and $p$ block elements. $d$ block elements are moderately reactive.

Except metal ions with $3 d^{0}$ and $3 d^{10}$ configurations, $d$ block metal compounds produce characteristic colours. This means transition metal ion complexes can produce coloured compounds. Most $d$ block metal ions form complex compounds.

## Electronegativity

Table below provides the electronegativity of $d$ block elements and can be used to understand the variation of electronegativity of $d$ block elements in the fourth period. Electronegativity increases with the atomic number. However, Mn and Zn are deviated from the trend due to their stable electron configuration. Due to the higher nuclear charge, $d$ block elements have higher electronegativity than that of the $s$ block elements.

| Element | Sc | Ti | V | Cr | Mn | Fe | Co | Ni | Cu | Zn |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| Electronegativity | 1.3 | 1.5 | 1.6 | 1.6 | 1.5 | 1.8 | 1.8 | 1.8 | 1.9 | 1.6 |

When an atom exhibits variable oxidation states, the higher oxidation state has higher electronegativity.

## Catalytic properties

Most transition metals and compounds can act as catalysts due to the presence of partially filed and empty $d$ orbitals. This makes d orbitals to accept or donate electrons. This property makes them effective components of catalysts. Pd for hydrogenation, $\mathrm{Pt} / \mathrm{Rh}$ for oxidation of ammonia to nitrogen oxide, and $\mathrm{V}_{2} \mathrm{O}_{5}$ for oxidation of $\mathrm{SO}_{2}$ to $\mathrm{SO}_{3}$ and $\mathrm{TiCl}_{3} / \mathrm{Al}\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)_{6}$ for the polymerization of ethene are some examples for the use of $d$ block element and its compound as a catalyst. Some popular organic reactions such as alkylation and acylation are done in the presence of transition metal ion as the catalyst.

## Colours of transition metal ions

Aqueous solutions of many transition metal ions can absorb radiation in the visible region of the electromagnetic spectrum to produce various colours. This ability is due to the presence of partially filled $d$ subshells. In contrast, metal ions of $s$ block are colourless because these ions have completely filled subshells. The following Table shows some of the colours of transition metal ions and oxoanions in aqueous solutions. For example, $\left[\mathrm{Co}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$ is pink, $\left[\mathrm{Mn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$ pale pink. In contrast, aqueous solutions of $\mathrm{Sc}^{3+}$ and $\mathrm{Zn}^{2+}$ are colourless due to the unavailability of partially filled $d$ orbitals. Also, ions with $d^{0}$ or $d^{10}$ configuration are coloureless when in an aqueous solution. Colours of $\mathrm{MnO}_{4}^{-}$ and $\mathrm{CrO}_{4}{ }^{2-}$ are not due to the electron transition of electrons among the $d$ orbitals. Colours of some elected oxoanions are given in Table 4.28.

Table 4.28 Colours of $d$ block metal ions and oxoanions in aqueous solutions. The number of $3 d$ and $4 s$ electrons are shown in brackets next to the metal ion.

| Ion | Colour | Ion | Colour |
| :--- | :--- | :--- | :--- |
| $\mathrm{Sc}^{3+}\left(d^{0} s^{0}\right)$ | Colourless | $\mathrm{Fe}^{3+}\left(d^{5} s^{0}\right)$ | Brown yellow |
| $\mathrm{Ti}^{4+}\left(d^{0} s^{0}\right)$ | Colourless | $\mathrm{Fe}^{2+}\left(d^{6} s^{0}\right)$ | Pale green |
| $\mathrm{Cr}^{3+}\left(d^{3} s^{0}\right)$ | Violet | $\mathrm{Co}^{2+}\left(d^{7} s^{0}\right)$ | Pink |
| $\mathrm{Mn}^{2+}\left(d^{5} s^{0}\right)$ | Pale pink | $\mathrm{Ni}^{2+}\left(d^{8} s^{0}\right)$ | Green |
|  |  | $\mathrm{Cu}^{2+}\left(d^{9} s^{0}\right)$ | Blue |
|  | $\mathrm{Cu}^{+}\left(d^{10} s^{0}\right)$ | Colourless |  |
|  | $\mathrm{Zn}^{2+}\left(d^{10} s^{0}\right)$ | Colourless |  |
|  |  |  |  |
| $\mathrm{Oxoanion}^{\mathrm{MnO}_{4}{ }^{-}}$ | Colour | Purple | $\mathrm{OxO}_{4}$ |
| $\mathrm{MnO}_{4}{ }^{2-}$ | Green | $\mathrm{Cr}_{2} \mathrm{O}_{7}{ }^{2-}$ | Colour |

### 4.10.3 Oxides of $\boldsymbol{d}$ block elements

First four elements form oxides by removing all valence electrons. Unlike main group elements, transition elements produce different oxidation states. Some $d$ block elements can form oxides in which metal atom presence with two different oxidation numbers. Both $\mathrm{Mn}_{3} \mathrm{O}_{4}$ and $\mathrm{Fe}_{3} \mathrm{O}_{4}$ are examples for binary oxides (which are formed with two oxidation numbers). $\mathrm{Mn}_{3} \mathrm{O}_{4}$ is a mixture of Mn (II) and Mn (III). Also, $\mathrm{Fe}_{3} \mathrm{O}_{4}$ is a mixture of Fe (II) and Fe (III) .

### 4.10.4 Chemistry of some selected $\boldsymbol{d}$ block oxides

## Chromium and manganese oxides

Properties of an oxide depend on the oxidation number. The bonding type depends on the oxidation number. The change in the bonding type explains the basis in the acid-base behaviour of metal oxides. For the compounds with high oxidation numbers have covalent bonding characteristics are acidic and the compounds with low oxidation numbers have ionic bonding characteristics are basic.

Table 4.29 Acid-base nature of chromium oxides

| Oxide | Acid-base nature | Oxidation <br> number |  |
| :--- | :--- | :--- | :--- |
| CrO | Weakly basic | +2 | low oxidation state |
| $\mathrm{Cr}_{2} \mathrm{O}_{3}$ | Amphoteric | +3 | moderate oxidation state |
| $\mathrm{CrO}_{2}$ | Weakly acidic | +4 |  |
| $\mathrm{CrO}_{3}$ | Acidic | +6 | high-oxidation state |

Generally, if the metal is in a lower oxidation state, the oxide is basic. Also, if the metal is in a moderate oxidation state, the oxide is amphoteric and metal oxides with higher oxidation state are acidic. This explains why the compounds in Tables 4.29 and $\mathbf{4 . 3 0}$ with lower oxidation states are more metallic while compounds with higher oxidation states are more non-metallic in properties.

Table 4.30 Acid-base nature of manganese oxides

| Oxide | Acid-base nature | Oxidation number |  |
| :--- | :--- | :--- | :--- |
| MnO | Basic | +2 | Low oxidation state |
| $\mathrm{Mn}_{2} \mathrm{O}_{3}$ | Weakly basic | +3 |  |
| $\mathrm{MnO}_{2}$ | Amphoteric | +4 | moderate oxidation state |
| $\mathrm{MnO}_{3}$ | Weakly acidic | +6 |  |
| $\mathrm{Mn}_{2} \mathrm{O}_{7}$ | Acidic | +7 | high-oxidation state |

## Reactions of some selected oxoanions of chromium

The yellow coloured chromate ion exists in neutral or basic conditions. Under the acidic conditions, it is converted to the orange coloured dichromate ion.

$$
2 \mathrm{CrO}_{4}{ }^{2-}(\mathrm{aq})+2 \mathrm{H}^{+}(\mathrm{aq}) \rightleftharpoons \mathrm{Cr}_{2} \mathrm{O}_{7}{ }^{2-}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

Even without partially filled $d$ subshells ( Cr at +6 oxidation state), both chromate and dichromate produce colours due to the electron charge transfer between Cr and O ligands. However, the explanation of this phenomena is not a part of the current syllabus.

The reduction of $\mathrm{Cr}^{6+}$ to $\mathrm{Cr}^{3+}$ happens only in acidic medium. In acidic medium, $\mathrm{CrO}_{4}{ }^{2-}$ ions will dimerized and converted into $\mathrm{Cr}_{2} \mathrm{O}_{7}{ }^{2-}$ ions. Therefore in acidic medium $\mathrm{Cr}^{6+}$ present only as $\mathrm{Cr}_{2} \mathrm{O}_{7}{ }^{2-}$.

Some important redox reactions of chromium oxoanions are given below.

$$
\begin{aligned}
& \mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}(\mathrm{aq})+3 \mathrm{H}_{2} \mathrm{~S}(\mathrm{~g})+8 \mathrm{H}^{+}(\mathrm{aq}) \longrightarrow 2 \mathrm{Cr}^{3+}(\mathrm{aq})+3 \mathrm{~S}(\mathrm{~s})+7 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \\
& \mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}(\mathrm{aq})+3 \mathrm{SO}_{2}(\mathrm{~g})+2 \mathrm{H}^{+}(\mathrm{aq}) \longrightarrow 2 \mathrm{Cr}^{3+}(\mathrm{aq})+3 \mathrm{SO}_{4}^{2-}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \\
& \mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}(\mathrm{aq})+6 \mathrm{Fe}^{2+}(\mathrm{g})+14 \mathrm{H}^{+}(\mathrm{aq}) \longrightarrow 2 \mathrm{Cr}^{3+}(\mathrm{aq})+6 \mathrm{Fe}^{3+}(\mathrm{aq})+7 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \\
& \mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}(\mathrm{aq})+\text { conc. } 14 \mathrm{HCl}(\mathrm{aq}) \longrightarrow 2 \mathrm{Cr}^{3+}(\mathrm{aq})+3 \mathrm{Cl}_{2}(\mathrm{~g})+8 \mathrm{Cl}^{-}(\mathrm{aq})+7 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})
\end{aligned}
$$

In $\mathrm{CrO}_{4}{ }^{2-}$, oxidation number Cr is +6 . Therefore it can act as an oxidizing agent. Under acidic conditions, $\mathrm{Cr}(\mathrm{IV})$ can be reduced to $\mathrm{Cr}(\mathrm{III})$.

$$
8 \mathrm{H}^{+}(\mathrm{aq})+\mathrm{CrO}_{4}{ }^{2-}(\mathrm{aq})+3 \mathrm{e} \longrightarrow \mathrm{Cr}^{3+}(\mathrm{aq})+4 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

## Reactions of manganese oxides and oxoanions

$\mathrm{KMnO}_{4}$ is a purple solid. Colour of $\mathrm{MnO}_{4}{ }^{-}$is due to the electron transfer process between central Mn atom and O ligands. Under acidic conditions, permanganate ion can act as a strong oxidizing agent. Colours of $\mathrm{MnO}_{2}$ and $\mathrm{KMnO}_{4}$ are given below.

Table 4.31 Colours of $\mathrm{MnO}_{2}$ and $\mathrm{KMnO}_{4}$

| Compound | Colour |
| :--- | :--- |
| $\mathrm{MnO}_{2}$ | Dark brown/black |
| $\mathrm{KMnO}_{4}$ | Purple |

Some important redox reactions of $\mathrm{MnO}_{4}{ }^{-}$are given below.
Under acidic conditions:

$$
\begin{aligned}
& 2 \mathrm{MnO}_{4}^{-}(\mathrm{aq})+5 \mathrm{H}_{2} \mathrm{O}_{2}(\mathrm{l})+6 \mathrm{H}^{+}(\mathrm{aq}) \longrightarrow 2 \mathrm{Mn}^{2+}(\mathrm{aq})+5 \mathrm{O}_{2}(\mathrm{~g})+8 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \\
& 2 \mathrm{MnO}_{4}^{-}(\mathrm{aq})+5 \mathrm{H}_{2} \mathrm{~S}(\mathrm{~g})+6 \mathrm{H}^{+}(\mathrm{aq}) \longrightarrow 2 \mathrm{Mn}^{2+}(\mathrm{aq})+5 \mathrm{~S}(\mathrm{~g})+8 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \\
& 2 \mathrm{MnO}_{4}^{-}(\mathrm{aq})+5 \mathrm{SO}_{2}(\mathrm{~g})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow 2 \mathrm{Mn}^{2+}(\mathrm{aq})+5 \mathrm{SO}_{4}^{2-}(\mathrm{aq})+4 \mathrm{H}^{+}(\mathrm{aq}) \\
& \mathrm{MnO}_{4}^{-}(\mathrm{aq})+5 \mathrm{Fe}^{2+}(\mathrm{aq})+8 \mathrm{H}^{+}(\mathrm{aq}) \longrightarrow 2 \mathrm{Mn}^{2+}(\mathrm{aq})+5 \mathrm{Fe}^{3+}(\mathrm{aq})+4 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \\
& 2 \mathrm{MnO}_{4}^{-}(\mathrm{aq})+1 \mathrm{I}^{-}(\mathrm{aq})+16 \mathrm{H}^{+}(\mathrm{aq}) \longrightarrow 2 \mathrm{Mn}^{2+}(\mathrm{aq})+5 \mathrm{I}_{2}(\mathrm{aq})+8 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \\
& 2 \mathrm{MnO}_{4}^{-}(\mathrm{aq})+5 \mathrm{NO}_{2}^{-}(\mathrm{aq})+6 \mathrm{H}^{+}(\mathrm{aq}) \longrightarrow 2 \mathrm{Mn}^{2+}(\mathrm{aq})+5 \mathrm{NO}_{3}^{-}(\mathrm{aq})+3 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \\
& 2 \mathrm{MnO}_{4}^{-}(\mathrm{aq})+\mathrm{conc}^{2} 16 \mathrm{HCl}(\mathrm{aq}) \longrightarrow 2 \mathrm{Mn}^{2+}(\mathrm{aq})+5 \mathrm{Cl}_{2}(\mathrm{~g})+6 \mathrm{Cl}^{-}(\mathrm{aq})+8 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \\
& 2 \mathrm{MnO}_{4}^{-}(\mathrm{aq})+5 \mathrm{C}_{2} \mathrm{O}_{4}{ }^{2-}(\mathrm{aq})+16 \mathrm{H}^{+}(\mathrm{aq}) \longrightarrow 2 \mathrm{Mn}^{2+}(\mathrm{aq})+10 \mathrm{CO}_{2}(\mathrm{~g})+8 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})
\end{aligned}
$$

In all these reactions, under acidic conditions, $\mathrm{MnO}_{4}^{-}$reduces to $\mathrm{Mn}^{2+}$.

Under dilute alkaline conditions:

$$
2 \mathrm{MnO}_{4}^{-}(\mathrm{aq})+\mathrm{I}^{-}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow 2 \mathrm{MnO}_{2}(\mathrm{~s})+\mathrm{IO}_{3}^{-}(\mathrm{aq})+2 \mathrm{OH}^{-}(\mathrm{aq})
$$

$$
2 \mathrm{MnO}_{4}^{-}(\mathrm{aq})+3 \mathrm{SO}_{3}{ }^{2-}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow 2 \mathrm{MnO}_{2}(\mathrm{~s})+3 \mathrm{SO}_{4}{ }^{2-}(\mathrm{aq})+2 \mathrm{OH}^{-}(\mathrm{aq})
$$

### 4.10.5 Coordination compounds of transition metal ions

Transition metal ions typically form coordination compounds. These coordination compounds consist of complex ions. These complex ions are built with a central metal ion and two or more surrounding monodentate ligands (there are ligands that form more than one bond with the central metal ion). For example, $\left[\mathrm{Ni}\left(\mathrm{NH}_{3}\right)_{6}\right] \mathrm{Cl}_{2}$ consists of the complex ion of $\left[\mathrm{Ni}\left(\mathrm{NH}_{3}\right)_{6}\right]^{2+}$ and the counter ion of $\mathrm{Cl}^{-}$(Figure 4.17).

Ligands (Lewis bases) can donate electrons to the central metal ion (Lewis acid) to form dative bonds with it.

Figure 4.17 A coordination compound
In this example, ammonia molecules are bonded as ammine ligands to the central metal ion of $\mathrm{Ni}^{2+}$. The charge of the complex ion can be easily determined using the following equation.

| The charge of the |
| :---: |
| complex |$=\quad$| Oxidation number of |
| :---: |
| the central metal atom |
| or the ion |$\quad+\quad$| Total charge of |
| :---: |
| all ligands |

## Determination of oxidation number of the central metal ion

The following method can be used to determine the oxidation number of the central metal ion of a coordination complex.

## Example 6.1

Calculate the oxidation number of the central metal ion in $\left[\mathrm{Ni}_{( }\left(\mathrm{H}_{2} \mathrm{O}\right)_{3} \mathrm{Cl}_{3}\right]^{-}$ complex ion.

Answer:

| The charge of the |
| :---: |
| complex |$=$| Oxidation number of |
| :---: |
| the central metal atom |
| or the ion |$+\quad+$| Total charge |
| :---: |
| of all ligands |

Charge of the complex ion $=-1$
Charges of the ligands = three $\mathrm{H}_{2} \mathrm{O}$ molecules: $3 \times 0=0$,

$$
\text { three } \mathrm{Cl}^{-} \text {ions: } 3(-1)=-3
$$

Using the equation;
$-1=$ Oxidation number of $\mathrm{Ni}+0+(-3)$
Oxidation number of $\mathrm{Ni}=+2$

### 4.10.6 Nomenclature of simple complex ions and compounds

Name of a metal complex provides information about the complex such as oxidation state of the central metal ion, types of ligands and the number. The rules used to write the name of a complex ion is proposed by IUPAC are given below.

## Naming of ligands

Name of an anion acting as a ligand in the complex ion can be obtained by removing the last letter of the anion name and adding ' $o$ ' letter to the end. Neutral molecules acting as ligands are usually given the name of the molecule. However, there are some exceptions and those are not discussed in the current G. C. E. (A/L) Chemistry syllabus.

## Anionic ligands

$\mathrm{Cl}^{-}$chlorido
$\mathrm{Br}^{-}$bromido
$\mathrm{CN}^{-}$cyanido
$\mathrm{OH}^{-}$hydroxido

## Neutral ligands

$\mathrm{NH}_{3}$ ammine
$\mathrm{H}_{2} \mathrm{O}$ aqua
CO carbonyl

Number of a particular ligand is indicated by prefixes. The used prefixes are $d i-$ two, tri - three, tetra - four, penta - five, hexa - six, etc.

## Naming of complex cations

Name of the complex ion must be written as a single word with no space and must only be written using lower case English letters. The oxidation number of the metal ion is indicated by Roman numerals within parentheses at the end of the metal name.

| e.g.: | $\left[\mathrm{Ni}\left(\mathrm{NH}_{3}\right)_{6}\right]^{2+}$ | hexaamminenickel(II) ion |
| :--- | :--- | :--- |
|  | $\left[\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}\right]^{2+}$ | tetraamminecopper(II) ion |
|  | $\left[\mathrm{Cr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}$ | hexaaquachromium(III) ion |

## Complex anions

For negatively charged complex ions (complex anions) the suffix 'ate' must be used after the name of the metal.

| e.g.: | $\left[\mathrm{CuCl}_{4}\right]^{2-}$ |
| :--- | :--- |
|  | $\left[\mathrm{CoCl}_{4}\right]^{2-}$ |$\quad$ tetrachloridocuprate(II) ion

Table 4.32 Names used for metals in anionic complexes

| Metal | Name used in <br> anionic complexes | Metal | Name used in <br> anionic complexes |
| :--- | :--- | :--- | :--- |
| Cr | chromate | Co | cobaltate |
| Cu | cuprate | Fe | ferrate |
| Mn | manganate | Ni | nickelate |
| Ag | argentate | Hg | mercurate |
| Au | aurate |  |  |

Name of a complex compound must have the name of the cation first and the anion name second. These two names must be separated by a space.
e.g.: $\left[\mathrm{Ni}\left(\mathrm{NH}_{3}\right)_{6}\right] \mathrm{Cl}_{2}$ - hexaamminenickel(II) chloride
$\mathrm{Na}_{2}\left[\mathrm{CoCl}_{4}\right]$ - sodium tetrachlorocoboltate(II)

## Coordination number

The number of coordination bonds formed between the central metal ion and ligands is defined as coordination number. Since some ligands can form more than one coordination bond with the central metal ion, it is incorrect to define the coordination number as the number of ligands coordinated to the central metal ion. The coordination number depends on the size, charge, nature of ligands and the electronic configuration of the central metal ion.

Table 4.33 Common coordination numbers of $d$ block ions

| $\mathbf{M}^{+}$ | Coordination <br> number | $\mathbf{M}^{2+}$ | Coordination <br> number | $\mathbf{M}^{3+}$ | Coordination <br> number |
| :--- | :--- | :--- | :--- | :--- | :--- |
| $\mathrm{Cu}^{+}$ | 2,4 | $\mathrm{Mn}^{2+}$ | 4,6 | $\mathrm{Sc}^{3+}$ | 6 |
|  | $\mathrm{Fe}^{2+}$ | 6 | $\mathrm{Cr}^{3+}$ | 4,6 |  |
|  | $\mathrm{Co}^{2+}$ | 4,6 | $\mathrm{Co}^{3+}$ | 4,6 |  |
|  | $\mathrm{Ni}^{2+}$ | 4,6 |  |  |  |
|  | $\mathrm{Cu}^{2+}$ | 4,6 |  |  |  |
|  | $\mathrm{Zn}^{2+}$ | 4,6 |  |  |  |

### 4.10.7 Factors affecting the colour of the complexes

Transition metal atoms and ions can produce coloured complexes. Colour of these complexes depends on the following factors. Examples which reflect the effect these factors are given in Table 4.34.

1. Central metal ion
2. The oxidation state of the central metal ion
3. Nature of the ligands

Table 4.34 Colours of transition metal ion complexes depends on the factors

1. Central metal ion

| $\mathrm{Mn}(\mathrm{II})$ | $\mathrm{Fe}(\mathrm{II})$ | $\mathrm{Co}($ II $)$ | $\mathrm{Ni}($ II $)$ | $\mathrm{Cu}(\mathrm{II})$ |
| :--- | :--- | :--- | :--- | :--- | :--- |
| $\left[\mathrm{Mn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$ | $\left[\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$ | $\left[\mathrm{Co}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$ | $\left[\mathrm{Ni}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$ | $\left[\mathrm{Cu}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$ |
| Pink | Pale-green | Pink | Green | Pale-blue |

2. The oxidation state of the central metal ion

| $\mathrm{Mn}(\mathrm{II})$ | $\mathrm{Mn}(\mathrm{III})$ | $\mathrm{Fe}($ II $)$ | $\mathrm{Fe}(\mathrm{III})$ |
| :--- | :--- | :--- | :--- |
| $\left[\mathrm{Mn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$ | $\left[\mathrm{Mn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}$ | $\left[\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$ | $\left[\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}$ |
| Pale-pink | Violet | Pale-green | Yellow |

Colour of $\left[\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}$ is depend on the anion
3. Nature of the ligand

| $\mathrm{H}_{2} \mathrm{O}$ | $\mathrm{OH}^{-}$ | $\mathrm{NH}_{3}$ | $\mathrm{Cl}^{-}$ |
| :--- | :--- | :--- | :--- |
| $\left[\mathrm{Co}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$ | $\left[\mathrm{Co}(\mathrm{OH})_{4}\right]^{2-}$ | $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)\right]^{2+}$ | $\left[\mathrm{Co}(\mathrm{Cl})_{4}\right]^{-}$ |
| Pink | Deep-blue | yellowish-brown | Blue |

Ability to form coloured compounds is a unique property of the transition metal elements. Colours of some common metal complexes are given in Table 4.33.
G.C.E. (A/L) CHEMISTRY: UNIT 6 Chemistry of $s$, $p$ and d block elements

Table 4.33 Metal complexes and colours

| Metal | Nature of the ligand |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
|  | $\mathrm{H}_{2} \mathrm{O}(\mathrm{l})$ | $\mathrm{OH}^{-}(\mathrm{aq})$ | $\mathrm{NH}_{3}(\mathrm{aq})$ | $\mathrm{Cl}^{-}(\mathrm{aq})$ |
| Cr | $\left[\mathrm{Cr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}$ <br> Violet | $\mathrm{Cr}(\mathrm{OH})_{3}$ <br> Blue-green ppt (precipitate) | $\mathrm{Cr}(\mathrm{OH})_{3}$ <br> Blue-green ppt | $\left[\mathrm{CrCl}_{6}\right]^{3-}$ <br> Blue-violet |

|  |  | With excess <br> $\mathrm{OH}^{-}$ <br> $\left[\mathrm{Co}(\mathrm{OH})_{4}\right]^{2-}$ <br> Deep-blue | $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+}$ <br> Brownish-red |  |
| Ni | $\left[\mathrm{Ni}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$ <br> Green | $\mathrm{Ni}(\mathrm{OH})_{2}$ <br> Green ppt | $\left[\mathrm{Ni}\left(\mathrm{NH}_{3}\right)_{6}\right]^{2+}$ <br> Blue | $\left[\mathrm{NiCl}_{4}\right]^{2-}$ <br> Yellow |
| Cu | $\left[\mathrm{Cu}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$ <br> Pale blue | $\mathrm{Cu}(\mathrm{OH})_{2}$ <br> Blue ppt | $\left[\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}\right]^{2+}$ <br> Deep blue | $\left[\mathrm{CuCl}_{4}\right]^{2-}$ <br> Yellow |
| Zn | $\left[\mathrm{Zn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$ <br> Colourless | $\mathrm{Zn}(\mathrm{OH})_{2}$ <br> White ppt | $\begin{aligned} & {\left[\mathrm{Zn}\left(\mathrm{NH}_{3}\right)_{4}\right]^{2+}} \\ & \text { Colourless } \end{aligned}$ | $\left[\mathrm{ZnCl}_{4}\right]^{2-}$ <br> Colourless |
|  |  | With excess <br> $\mathrm{OH}^{-}$ <br> $\left[\mathrm{Zn}(\mathrm{OH})_{4}\right]^{2-}$ <br> Colourless |  |  |

## Reactions of $\left[\mathrm{Cr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}$

With aqueous $\mathrm{NH}_{3}$, the violet colour $\left[\mathrm{Cr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}$ aqueous solution will be turned into a blue-green gelatinous precipitate.

$$
\left[\mathrm{Cr}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}+3 \mathrm{NH}_{3}(\mathrm{aq}) \longrightarrow \mathrm{Cr}(\mathrm{OH})_{3}(\mathrm{~s})+3 \mathrm{NH}_{4}^{+}(\mathrm{aq})+3 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

## Reactions of $\left[\mathrm{Co}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$

With strong base $(\mathrm{NaOH})$; the pink colour $\left[\mathrm{Co}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$ aqueous solution turns into pink precipitate.

$$
\left[\mathrm{Co}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}(\mathrm{aq})+2 \mathrm{OH}^{-}(\mathrm{aq}) \longrightarrow \mathrm{Co}(\mathrm{OH})_{2}(\mathrm{~s})+6 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

$\mathrm{Co}(\mathrm{OH})_{2}$ is a pink precipitate. With excess concentrated hydroxide ion solutions, a deep blue solution is formed.

$$
\mathrm{Co}(\mathrm{OH})_{2}(\mathrm{~s})+2 \mathrm{OH}^{-}(\mathrm{aq}) \longrightarrow\left[\mathrm{Co}(\mathrm{OH})_{4}\right]^{2-}(\mathrm{aq})
$$

With $\mathrm{NH}_{3}$

$$
\left[\mathrm{Co}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}(\mathrm{aq})+6 \mathrm{NH}_{3}(\mathrm{aq}) \longrightarrow\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right]^{2+}(\mathrm{aq})+6 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

Initially, the pink colour $\left[\mathrm{Co}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$ forms a pink colour $\mathrm{Co}(\mathrm{OH})_{2}$ precipitate with limited amount of concentrated $\mathrm{NH}_{3}$ and on further addition of concentrated $\mathrm{NH}_{3}$ it forms a yellow colour $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right]^{2+}$ complex ion. However due to the auto-oxidation, $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right]^{2+}$ complex convert to a brown colour $\left[\mathrm{Co}\left(\mathrm{NH}_{3}\right)_{6}\right]^{3+}$. Because of this, the solution appears as yellowish-brown solution.

With conc. HCl , pink colour solution turns into a blue colour solution.

$$
\left.\mathrm{Co}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}(\mathrm{aq})+4 \mathrm{Cl}^{-}(\mathrm{aq}) \longrightarrow\left[\mathrm{CoCl}_{4}\right]^{2-}(\mathrm{aq})+6 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

## Reactions of $\left.\left[\mathrm{Ni}_{\left(\mathrm{H}_{2} \mathrm{O}\right.}\right)_{6}\right]^{\mathbf{2 +}}$

With a strong base, the green colour $\left[\mathrm{Ni}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$ aqueous solution turns into a green precipitate.

$$
\left[\mathrm{Ni}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}(\mathrm{aq})+2 \mathrm{OH}^{-}(\mathrm{aq}) \longrightarrow \mathrm{Ni}(\mathrm{OH})_{2}(\mathrm{~s})+6 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

With excess $\mathrm{NH}_{3}(\mathrm{aq})$, the green colour $\left[\mathrm{Ni}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$ solution turns into a deep blue solution.

$$
\left[\mathrm{Ni}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}(\mathrm{aq})+6 \mathrm{NH}_{3}(\mathrm{aq}) \longrightarrow\left[\mathrm{Ni}^{( }\left(\mathrm{NH}_{3}\right)_{6}\right]^{2+}(\mathrm{aq})+6 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

With concentrated HCl , green colour solution turns into a yellow colour solution.

$$
\left[\mathrm{Ni}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}(\mathrm{aq})+4 \mathrm{Cl}^{-}(\mathrm{aq}) \longrightarrow\left[\mathrm{NiCl}_{4}\right]^{2-}(\mathrm{aq})+6 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

## Reactions of $\left[\mathbf{M n}\left(\mathbf{H}_{2} \mathbf{O}\right)_{6}\right]^{2+}$

With strong base, pale pink colour $\left[\mathrm{Mn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$ aqueous solution turns to a white/ cream colour precipitate.

$$
\left[\mathrm{Mn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}(\mathrm{aq})+2 \mathrm{OH}^{-}(\mathrm{aq}) \longrightarrow \mathrm{Mn}(\mathrm{OH})_{2}(\mathrm{~s})+6 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

With aqueous $\mathrm{NH}_{3}$, the pale pink colour solution turns into a white/ cream colour precipitate.

$$
\left[\mathrm{Mn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}(\mathrm{aq})+2 \mathrm{NH}_{3}(\mathrm{aq}) \longrightarrow \mathrm{Mn}(\mathrm{OH})_{2}(\mathrm{~s})+2 \mathrm{NH}_{4}{ }^{+}(\mathrm{aq})+4 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

## Reactions of $\left[\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}$

With strong base, yellow colour $\left[\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}$ aqueous solution turns into a reddish-brown precipitate.

$$
\left[\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}(\mathrm{aq})+3 \mathrm{OH}^{-}(\mathrm{aq}) \longrightarrow \mathrm{Fe}(\mathrm{OH})_{3}(\mathrm{~s})+6 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

With aqueous $\mathrm{NH}_{3}$, yellow colour $\left[\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}$ aqueous solution turns into a reddishbrown precipitate.

$$
\left[\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}(\mathrm{aq})+3 \mathrm{NH}_{3}(\mathrm{aq}) \longrightarrow \mathrm{Fe}(\mathrm{OH})_{3}(\mathrm{~s})+3 \mathrm{NH}_{4}^{+}(\mathrm{aq})+3 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

## Reactions of $\left[\mathrm{Cu}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$

With strong base, the blue colour $\left[\mathrm{Cu}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$ aqueous solution turns into a blue precipitate.

$$
\left[\mathrm{Cu}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}(\mathrm{aq})+2 \mathrm{OH}^{-}(\mathrm{aq}) \longrightarrow \mathrm{Cu}(\mathrm{OH})_{2}(\mathrm{~s})+6 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

With a limited amount of aqueous $\mathrm{NH}_{3}$, blue colour solution turns into a blue precipitate.

$$
\left[\mathrm{Cu}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}(\mathrm{aq})+2 \mathrm{NH}_{3}(\mathrm{aq}) \longrightarrow \mathrm{Cu}(\mathrm{OH})_{2}(\mathrm{~s})+2 \mathrm{NH}_{4}^{+}(\mathrm{aq})+4 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

With excess aqueous $\mathrm{NH}_{3}$, blue colour solution turns into a deep blue colour complex.

$$
\left[\mathrm{Cu}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}(\mathrm{aq})+4 \mathrm{NH}_{3}(\mathrm{aq}) \longrightarrow\left[\mathrm{Cu}\left(\mathrm{NH}_{3}\right)_{4}\right]^{2+}(\mathrm{aq})+6 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

With concentrated HCl , blue colour solution turns into a yellow colour solution.

$$
\left[\mathrm{Cu}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}(\mathrm{aq})+4 \mathrm{Cl}^{-}(\mathrm{aq}) \longrightarrow\left[\mathrm{CuCl}_{4}\right]^{2-}(\mathrm{aq})+6 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

## Reactions of $\left[\mathbf{Z n}\left(\mathbf{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$

With limited amount of strong base, colourless $\left[\mathrm{Zn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}$ aqueous solution turns into a white precipitate.

$$
\left[\mathrm{Zn}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{2+}(\mathrm{aq})+2 \mathrm{OH}^{-}(\mathrm{aq}) \longrightarrow \mathrm{Zn}(\mathrm{OH})_{2}(\mathrm{~s})+6 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

With excess strong base; white precipitate turns into a colourless clear solution.

$$
\mathrm{Zn}(\mathrm{OH})_{2}(\mathrm{~s})+2 \mathrm{OH}^{-}(\mathrm{aq}) \longrightarrow\left[\mathrm{Zn}(\mathrm{OH})_{4}\right]^{2-}(\mathrm{aq})
$$

The colourless solution turns into a white precipitate, then with excess base, the precipitate dissolves to form a colourless solution.

### 4.10.8 Importance of $\boldsymbol{d}$ block elements

1. Transition metals are good conductors $(\mathrm{Au}, \mathrm{Ag}$ and Cu$)$, and are also malleable, ductile, and lustrous. Transition metals can be mixed together to produce alloys since they have similar atomic sizes. These alloys are used since the ancient time for various purposes. Production of alloys can change the properties of metals.
2. Cobalt isotope ${ }^{60} \mathrm{Co}$ is widely used as a radiation source in radiotherapy.
3. Transition metal atoms and ions are used to develop compounds with catalytic properties that are widely used in different industries as catalyst.
4. Since transition metals can form various coloured compounds, they are used as pigments for the production of paint. They are also used to produce coloured glasses and glass bottles.
5. $\quad d$ block elements such as Ni and Cd are used to produce rechargeable batteries.
6. They are used in the production of compounds such as cadmium telluride $(\mathrm{CdTe})$ and copper indium diselenide in photovoltaic cells. The solar cell is an example for a photovoltaic cell.

### 4.10.9 Identification tests for selected cations of $\boldsymbol{d}$ block elements

1. $\mathrm{Fe}^{2+}$

Formation of $\mathrm{KFe}\left[\mathrm{Fe}(\mathrm{CN})_{6}\right]$, a dark-blue precipitate of with $\mathrm{K}_{3}\left[\mathrm{Fe}(\mathrm{CN})_{6}\right]$, can be used to identify $\mathrm{Fe}^{2+}$.

$$
\mathrm{Fe}^{2+}(\mathrm{aq})+\mathrm{K}_{3}\left[\mathrm{Fe}(\mathrm{CN})_{6}\right](\mathrm{aq}) \longrightarrow \mathrm{KFe}\left[\mathrm{Fe}(\mathrm{CN})_{6}\right](\mathrm{s})+2 \mathrm{~K}^{+}(\mathrm{aq})
$$

2. $\mathrm{Fe}^{3+}$

Formation of $\mathrm{Fe}_{4}\left[\mathrm{Fe}(\mathrm{CN})_{6}\right]_{3}$, Prussian-blue complex of with $\mathrm{K}_{4}\left[\mathrm{Fe}(\mathrm{CN})_{6}\right]$, can be used to identify $\mathrm{Fe}^{3+}$.

$$
4 \mathrm{Fe}^{3+}(\mathrm{aq})+\mathrm{K}_{4}\left[\mathrm{Fe}(\mathrm{CN})_{6}\right](\mathrm{aq}) \longrightarrow \mathrm{Fe}_{4}\left[\mathrm{Fe}(\mathrm{CN})_{6}\right]_{3}(\mathrm{~s})+4 \mathrm{~K}^{+}(\mathrm{aq})
$$

Formation of red colour, $\left[\mathrm{Fe}(\mathrm{SCN})\left(\mathrm{H}_{2} \mathrm{O}\right)_{5}\right]^{2+}$ complex with a slightly acidic $\mathrm{NH}_{4} \mathrm{SCN}$ solution, can be used to identify $\mathrm{Fe}^{3+}$.

$$
\left[\mathrm{Fe}\left(\mathrm{H}_{2} \mathrm{O}\right)_{6}\right]^{3+}+\mathrm{NH}_{4} \mathrm{SCN}(\mathrm{aq}) \longrightarrow\left[\mathrm{Fe}(\mathrm{SCN})\left(\mathrm{H}_{2} \mathrm{O}\right)_{5}\right]^{2+}+\mathrm{NH}_{4}{ }^{+}(\mathrm{aq})
$$

3. $\mathrm{Cr}^{3+}$

Oxidation of $\mathrm{Cr}^{3+}$ to yellow colour solution of $\mathrm{CrO}_{4}{ }^{2-}$
Addition of excess of sodium hydroxide to a $\mathrm{Cr}^{3+}$ solution followed by a few milliliters of $6 \%$ hydrogen peroxide form a yellow colour solution of $\mathrm{CrO}_{4}{ }^{2-}$.

$$
\mathrm{Cr}^{3+}(\mathrm{aq})+3 \mathrm{NaOH} \longrightarrow \mathrm{Cr}(\mathrm{OH})_{3}(\mathrm{~s})+3 \mathrm{Na}^{+}(\mathrm{aq})
$$

$$
2 \mathrm{Cr}(\mathrm{OH})_{3}(\mathrm{~s})+3 \mathrm{H}_{2} \mathrm{O}_{2}(\mathrm{aq}) \longrightarrow 2 \mathrm{CrO}_{4}{ }^{2^{-}}(\mathrm{aq})+4 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})+4 \mathrm{H}^{+}(\mathrm{aq})
$$

## Message from the Director General

The National Institute of Education takes opportune steps from time to time for the development of quality in education. Preparation of supplementary resource books for respective subjects is one such initiative.

Supplementary resource books have been composed by a team of curriculum developers of the National Institute of Education, subject experts from the national universities and experienced teachers from the school system. Because these resource books have been written so that they are in line with the G. C. E. (A/L) new syllabus implemented in 2017, students can broaden their understanding of the subject matter by referring these books while teachers can refer them in order to plan more effective learning teaching activities.

I wish to express my sincere gratitude to the staff members of the National Institute of Education and external subject experts who made their academic contribution to make this material available to you.

Dr. (Mrs.) T. A. R. J. Gunasekara

Director General
National Institute of Education
Maharagama.

## Message from the Director

Since 2017, a rationalized curriculum, which is an updated version of the previous curriculum is in effect for the G.C.E (A/L) in the general education system of Sri Lanka. In this new curriculum cycle, revisions were made in the subject content, mode of delivery and curricular materials of the G.C.E. (A/L) Physics, Chemistry and Biology. Several alterations in the learning teaching sequence were also made. A new Teachers' Guide was introduced in place of the previous Teacher's Instruction Manual. In concurrence to that, certain changes in the learning teaching methodology, evaluation and assessment are expected. The newly introduced Teachers' Guide provides learning outcomes, a guideline for teachers to mould the learning events, assessment and evaluation.

When implementing the previous curricula, the use of internationally recognized standard textbooks published in English was imperative for the Advanced Level science subjects. Due to the contradictions of facts related to the subject matter between different textbooks and inclusion of the content beyond the limits of the local curriculum, the usage of those books was not convenient for both teachers and students. This book comes to you as an attempt to overcome that issue.

As this book is available in Sinhala, Tamil, and English, the book offers students an opportunity to refer the relevant subject content in their mother tongue as well as in English within the limits of the local curriculum. It also provides both students and teachers a source of reliable information expected by the curriculum instead of various information gathered from the other sources.

This book authored by subject experts from the universities and experienced subject teachers is presented to you followed by the approval of the Academic Affairs Board and the Council of the National Institute of Education. Thus, it can be recommended as a material of high standard.

Dr. A. D. A. De Silva

Director
Department of Science

## A Note to Students from the Authors

This book has been written to specifically cover the contents of the Organic Chemistry units of the G.C.E. (A/L) Chemistry syllabus. The core content of the syllabus is concerned with the characteristic reactions of selected classes of compounds. Modern Organic Chemistry is founded on the basic idea that the chemical behavior of a compound can be accounted for by its structure. The book emphasizes the application of a limited number of fundamental concepts to rationalize and understand all the reactions covered. Simple descriptions of mechanisms are given and explained where relevant. Only the reactions specified in the syllabus are covered, and for any given reaction only the main product/products are considered. Experimental conditions are given only if they are critical.

The authors hope that the book will be useful to students to understand and appreciate organic chemistry, and to move away from rote memorization of isolated facts. This will build a solid foundation for more advanced study if the student wishes to do so.

1.2.1.1 Alcohol
1.2.1.2 Ethers
1.2.1.3 Aldehyde
1.2.1.4 Ketones
1.2.1.5 Alkyl halides
1.2.1.6 Carboxylic acids
1.2.1.7 Acid halides, esters and amides (derivatives of carboxylic acids)
1.2.1.8 Amines
1.3 IUPAC nomenclature of organic compounds ..... 07
1.3.1 IUPAC Nomenclature
1.3.2 Alkane hydrocarbons
1.3.3 Nomenclature of branched chain alkanes
1.3.4 Nomenclature of alkene and alkyne hydrocarbons
1.3.5 IUPAC nomenclature of compounds other than hydrocarbons
1.3.6 IUPAC nomenclature of compounds containing more than one functional group
1.4 Isomerism ..... 21
1.4.1 Constitutional (structural) isomerism
1.4.2 Stereoisomerism
Unit 8 Hydrocarbons and halohydrocarbons ..... 26-52
2.1 Structure, physical properties and nature of bonds of aliphatic hydrocarbon ..... 27
2.1.1 Properties of alkanes
2.1.2 Structure of alkanes
2.1.3 Properties of alkenes and alkynes
2.1.4 Structure of alkenes
2.1.5 Structure of alkynes
2.2 Chemical reactions of alkanes, alkenes and alkynes in terms of their structures ..... 33
2.2.1 Reactions of alkanes
2.2.1.1 Chlorination of alkanes
2.2.2 Reactions of alkenes
2.2.2.1 Addition of hydrogen halides ( $\mathrm{HCl}, \mathrm{HBr}$ or HI )
2.2.2.2 Addition of bromine to alkenes
2.2.2.3 Addition of sulphuric acid and the hydrolysis of the addition product
2.2.2.4 Catalytic addition of hydrogen (Hydrogenation)
2.2.2.5 Reaction of alkenes with cold, alkaline, dilute potassium permanganate
2.2.3 Reactions of alkynes
2.2.3.1 Addition of bromine
2.2.3.2 Addition of hydrogen halides
2.2.3.3 Addition of water
2.2.3.4 Catalytic addition of hydrogen (Hydrogenation)
2.2.4 Acidic nature of alkynes with terminal hydrogen
2.3 The nature of bonding in benzene ..... 41
2.3.1 Structure of benzene
2.3.2 Stability of benzene
2.4 Characteristic reactions of benzene exemplifying its stability ..... 44
2.4.1 Electrophilic substitution reactions of benzene
2.4.1.1 Nitration
2.4.1.2 Friedel - Crafts alkylation
2.4.1.3 Friedel - Crafts acylation
2.4.1.4 Halogenation
2.4.2 Resistance of benzene ring towards oxidation
2.4.3 Resistance of benzene ring towards hydrogenation
2.5 Directing ability of substituent groups of mono substituted benzene. ..... 49
2.5.1 Ortho para directing groups
2.5.2 Meta directing groups
2.6 Structure and reactions of alkyl halides ..... 49
2.7 Nucleophilic substitution reactions of alkyl halides in terms of the timing of bond making and bond breaking steps ..... 51
Unit 9 Oxygen containing organic compounds ..... 53-73
3.1 Structure, properties and reactions of alcohols. ..... 54
3.1.1 Classification of monohydric alcohols
3.1.2 Physical properties
3.1.3 Reactions of alcohols
3.1.3.1 Reactions involving cleavage of O-H bond
3.1.3.2 Nucleophilic substitution reactions involving cleavage of C-O bond
3.1.3.3 Elimination reaction
3.1.3.4 Oxidation of alcohols
3.2 Structure, properties and reactions of phenols ..... 58
3.2.1 Acidity of phenols
3.2.2 Reactions involving cleavage of the O-H bond
3.2.3 Non-occurrence of nucleophilic substitution reactions by breaking C-O bond
3.3 Reactivity of the benzene ring in phenols ..... 59
3.3.1 Reaction of phenol with $\mathrm{Br}_{2}$
3.3.2 Nitration of phenol
3.4 Structure, properties and reactions aldehydes and ketones ..... 60
3.4.1 Physical properties
3.4.2 Reactions of aldehydes and ketones
3.4.3 Nucleophilic addition reactions
3.4.3.1 Addition of HCN to aldehydes and ketones
3.4.3.2 Reaction with Grignard reagents
3.4.3.3 Reaction with 2,4-dinitrophenyl hydrazine (2,4-DNP or Brady reagent)
3.4.4 Self-condensation reactions of aldehydes and ketones
3.4.5 Reduction of aldehydes and ketones by lithium aluminium hydride $\left(\mathrm{LiAlH}_{4}\right)$ or sodium borohydride $\left(\mathrm{NaBH}_{4}\right)$
3.4.6 Reduction of aldehydes and ketones by $\mathrm{Zn}(\mathrm{Hg}) /$ conc. HCl (Clemmensonreduction)
3.4.7 Oxidation of aldehydes
3.4.7.1 Oxidation by Tollens reagent
3.4.7.2 Oxidation by Fehling solution
3.4.7.3 Oxidation by acidified potassium dichromate or acidified chromic oxide or acidified potassium permanganate
3.5 Structure properties and reactions of carboxylic acids ..... 66
3.5.1 Physical properties
3.5.2 Comparison of the reactivity pattern of -COOH group with $>\mathrm{C}=\mathrm{O}$ group in aldehydes and ketones and - OH group in alcohols and phenols
3.5.2.1 Reactions involving cleavage of the $\mathrm{O}-\mathrm{H}$
3.5.2.2 Reactions involving cleavage of the $\mathrm{C}-\mathrm{O}$ bond
3.5.2.3 Reduction of carboxylic acids with $\mathrm{LiAlH}_{4}$
3.6 Reactions of carboxylic acid derivatives. ..... 70
3.6.1 Reactions of acid chloride
3.6.1.1 Reaction with aqueous sodium hydroxide
3.6.1.2 Reaction with water
3.6.1.3 Reaction with alcohols and phenols
3.6.1.4 Reaction with ammonia and primary amines
3.6.2 Reactions of esters
3.6.2.1 Reaction with dilute mineral acids
3.6.2.2 Reaction with aqueous sodium hydroxide
3.6.2.3 Reaction with Grignard reagent
3.6.2.4 Reduction by $\mathrm{LiAlH}_{4}$
3.6.3 Reactions of amides
3.6.3.1 Reaction with aqueous sodium hydroxide
3.6.3.2 Reduction with $\mathrm{LiAlH}_{4}$
Unit 10 Nitrogen containing organic compounds ..... 74-80
4.1 Structure, properties and reactions of primary amines and aniline. ..... 75
4.1.1 Classification of amines
4.1.2 Reactivity of the benzene ring of aniline
4.1.3 Reactions of primary amines
4.1.3.1 Reaction of amines with alkyl halides
4.1.3.2 Reaction of amines with aldehydes and ketones
4.1.3.3 Reaction of amines with acid chloride
4.1.3.4 Reaction of amines with nitrous acid $\left(\mathrm{NaNO}_{2} / \mathrm{HCl}\right)$
4.2 Basicity of amines. ..... 77
4.2.1 Basicity of amines versus alcohols
4.2.2 Basicity of primary aliphatic amines and aniline
4.2.3 Basicity of amines compared to amide
4.3 Reactions of aromatic diazonium salts. ..... 78
4.3.1 Reactions in which the diazonium group is replaced by another atom or a group
4.3.3.1 Reaction of diazonium salts with water
4.3.3.2 Reaction of diazonium salts with hypophosphorous acid $\left(\mathrm{H}_{3} \mathrm{PO}_{2}\right)$
4.3.3.3 Reaction of diazonium salts with CuCl and CuBr
4.3.3.4 Reaction of diazonium salts with CuCN
4.3.3.5 Reaction of diazonium salts with KI
4.3.2 Reactions in which the diazonium ion acts as an electrophile

## Introduction

Organic Chemistry is the chemistry of compounds of carbon. In these compounds, carbon atoms form the skeleton or backbone of the molecule. In addition to carbon, organic compounds usually contain hydrogen. Oxygen, nitrogen, sulphur, phosphorus and halogens are also found in certain organic compounds. These compounds can be natural or synthetic. Organic compounds form an essential component of all living organisms and play a central role in metabolic processes. Organic compounds also form an essential component in many of the materials that are essential for our daily life such as food, plastic items, textiles, cosmetics and medicines. The variety and number of compounds formed by carbon is very large compared to the compounds formed by other elements in the periodic table.

### 1.1 Organic chemistry in day to day life

Organic compounds are associated with nearly every aspect of our existence. For example:
Food components: Carbohydrates, fats, proteins
Plastic materials: PVC, polythene, polystyrene, polyesters, nylon
Medicines: Paracetamol, aspirin, penicillin, amoxicillin
Fuels: Petrol, diesel, kerosene, LP gas

### 1.1.1 Why carbon can form a large number of organic compounds with vast structural diversity? Uniqueness of carbon

Carbon-carbon and carbon-hydrogen bonds are the predominant bonds found in organic compounds. Between two C atoms strong single bonds, double bonds and triple bonds can be formed. The small electronegativity difference between C and H also leads to the formation of $\mathrm{C}-\mathrm{H}$ covalent bonds. The presence of 4 electrons in its valence shell enables it to form 4 covalent bonds which include carbon-carbon double bonds and triple bonds. Due to these reasons, carbon is capable of forming linear and branched chains and rings leading to compounds with diverse carbon skeletons. As carbon can also form bonds with O, N, S, P and halogens, this leads to the formation of an enormous variety of organic compounds having a wide range of molecular weights. When compared to Si which is also in the fourth group of the periodic table to which C belongs, the $\mathrm{C}-\mathrm{C}$ and $\mathrm{C}-\mathrm{H}$ bonds possess higher bond energies than $\mathrm{Si}-\mathrm{Si}$ and $\mathrm{Si}-\mathrm{H}$ bonds. Some bond energies relevant to the discussion above are shown in Table 1.1.

Table 1.1 Bond energies of some bonds with C and Si

| Bond | Bond energy/ $\mathbf{k J ~ m o l}^{-1}$ |
| :--- | :--- |
| $\mathrm{C}-\mathrm{C}$ | 346 |
| $\mathrm{C}=\mathrm{C}$ | 610 |
| $\mathrm{C} \equiv \mathrm{C}$ | 835 |
| $\mathrm{C}-\mathrm{H}$ | 413 |
| $\mathrm{Si}-\mathrm{Si}$ | 226 |
| $\mathrm{Si}-\mathrm{H}$ | 318 |
|  | 2 |

## G.C.E. (A/L) CHEMISTRY: UNIT 7 Basic Concepts of Organic Chemistry

### 1.2 Diversity of organic compounds in terms of functional groups

Some organic compounds contain only C and H as the constituent elements. They are known as hydrocarbons. On the basis of the structure, hydrocarbons are divided into two main groups called aliphatic and aromatic. Hydrocarbons consisting of only open carbon chains are called as acyclic aliphatic hydrocarbons while those with cyclic carbon chains are called alicyclic hydrocarbons. The aliphatic hydrocarbons are classified as alkanes, alkenes, and alkynes. The cyclic organic compounds which are stabilized by forming a cyclic delocalized cloud of $\pi$ electrons are called aromatic compounds. Benzene which is indicated by the molecular formula $\mathrm{C}_{6} \mathrm{H}_{6}$ is the simplest of aromatic hydrocarbon compounds. The classification of hydrocarbons is shown in the Figure 1.1 with common examples of each type.

Figure 1.1 Classification of hydrocarbons
Note: Cycloalkanes, cycloalkenes and cycloalkynes are not included in the current G.C.E. (A/L) syllabus.

Compounds are classified according to the functional groups present in their molecules. A functional group is a group of atoms in a molecule where most of its reactions take place. Apart from the carbon-carbon double bond and carbon-carbon triple bond, a functional group contains one or more heteroatoms such as nitrogen and oxygen. Common functional groups and the names of the corresponding homologous series are given in Table 1.2.

Table 1.2 Functional groups in organic compounds

| Functional group | Name of the homologous series | Example with name |  |
| :---: | :---: | :---: | :---: |
| $\begin{aligned} & { }^{\prime}=C^{\prime} \\ & \hline \end{aligned}$ | Alkene |  | propene |
| $-\mathrm{C}=\mathrm{C}-$ | Alkyne | $\mathrm{H}-\mathrm{C}=\mathrm{C}-\mathrm{H}$ | ethyne |
| $-\mathrm{OH}$ | Alcohol | $\mathrm{CH}_{3} \mathrm{CH}_{2}-\mathrm{OH}$ | ethanol |
|  | Aldehyde | $\mathrm{CH}_{3}-\mathrm{Cl}_{\mathrm{H}}^{\mathbf{\prime \prime}}$ | ethanal |
| $-c^{\prime \prime}$ | Ketone |  | propanone |
|  | Carboxylic acid |  | ethanoic acid |
| $-\frac{0}{C^{\prime \prime}}$ | Acid $\quad \mathrm{X}=\mathrm{Cl}$; acid halide chloride $\mathrm{X}=\mathrm{Br}$; acid bromide |  | ethanoyl chloride |
| $-\frac{C^{\prime}}{O-R}$ | Ester |  | methyl ethanoate |
| $\mathrm{R}_{1}-\mathrm{O}_{\mathrm{R}_{2}}$ | Ether | $\mathrm{CH}_{3}-\mathrm{O}_{\mathrm{CH}_{2} \mathrm{CH}_{3}}$ | ethylmethyl ether |
| $\begin{gathered} \mathrm{O} \\ -\mathrm{C}^{\prime \prime} \\ \mathrm{NH}_{2} \end{gathered}$ | Amide |  | ethanamide |
| $\mathrm{R}_{1}-N_{\mathrm{N}_{3}}^{\mathrm{R}_{2}}$ | Amine | $\begin{gathered} \mathrm{CH}_{3} \mathrm{CH}_{2}-\mathrm{NH}_{2} \\ \mathrm{CH}_{3} \mathrm{CH}_{2}-\mathrm{NH} \\ \stackrel{C H}{3} \end{gathered}$ | ethylamine ethylmethylamine |
| - $\mathrm{C}=\mathrm{N}$ | Nitrile | $\mathrm{CH}_{3} \mathrm{CH}_{2}-\mathrm{C} \equiv \mathrm{N}$ | propanenitrile |
| -x | $\begin{aligned} & \text { X = Cl; alkyl } \\ & \text { chloride } \\ & \text { X = Br; alkyl } \\ & \text { bromide } \\ & \text { X = I; alkyl iodide } \end{aligned}$ | $\mathrm{CH}_{3} \mathrm{CH}_{2}-\mathrm{Cl}$ | chloroethane |
|  |  | $\mathrm{CH}_{3} \mathrm{CH}_{2}-\mathrm{Br}$ | bromoethane |

Note: Alkenes, alkynes, ethers and alkyl halides are not considered as functional groups in the IUPAC nomenclature system.

### 1.2.1 Classes of compounds with functional groups containing heteroatoms

### 1.2.1.1 Alcohol

Alcohols are compounds containing a hydroxyl group ( -OH ) attached to an alkyl group. Some examples are given in Figure 1.2.

Figure 1.2 Some examples for alcohols
Note: An alkyl group is formally derived from an alkane by the removal of a hydrogen atom.

### 1.2.1.2 Ethers

Ethers are compounds containing an oxygen atom attached to two alkyl groups. Some examples are given in Figure 1.3.

dimethyl ether

ethyl methyl ether

diethyl ether

Figure 1.3 Some examples for ethers

### 1.2.1.3 Aldehyde

Aldehydes are compounds containing a carbonyl $(\mathrm{C}=\mathrm{O})$ group attached to an H atom. Some examples are given in Figure 1.4.

acetaldehyde

Figure 1.4 Some examples for aldehydes

### 1.2.1.4 Ketones

Ketones are compounds containing a carbonyl $(\mathrm{C}=\mathrm{O})$ group attached to two carbon atoms each of which may belong to an alkyl or aryl group. Some examples are given in Figure 1.5.

acetone

ethyl methyl ketone

acetophenone

Figure 1.5 Some examples for ketones

## G.C.E. (A/L) CHEMISTRY: UNIT 7 Basic Concepts of Organic Chemistry

### 1.2.1.5 Alkyl halides

Alkyl halides are compounds containing a halogen atom bonded to an alkyl group. Some examples are given in Figure 1.6.

|  |  | $\stackrel{\text { Cl }}{\mathrm{Cl}} \mathrm{CH}_{3} \mathrm{I}$ |
| :---: | :---: | :---: |
| methyl iodide | $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{Br}$ | $\mathrm{CH}_{3} \mathrm{CHCH}_{3}$ |
| ethyl bromide | iso-propyl chloride |  |

Figure 1.6 Some examples for alkyl halides
Note: Compounds containing a halogen atom joined to an aromatic ring are called aryl halides.

### 1.2.1.6 Carboxylic acids

Carboxylic acids are compounds containing the carboxylic acid (COOH) group. Some examples are given in Figure 1.7.

Figure 1.7 Some examples for carboxylic acids

### 1.2.1.7 Acid halides, esters and amides (derivatives of carboxylic acids)

Acid halides are compounds containing the COX group where X is a halogen atom. Esters are compounds containing the COOR group and amides are compounds containing the $\mathrm{CONH}_{2}$ group. Some examples are given in Figure 1.8.

acetyl chloride

ethyl acetate

acetamide

Figure 1.8 Some examples for derivatives of carboxylic acids
Note: Acid halides, esters and amides are derived by replacing the OH group in the COOH group by halogen, OR and $\mathrm{NH}_{2}$ groups respectively.

### 1.2.1.8 Amines

Amines are compounds derived formally from ammonia by replacing its H atoms either by alkyl groups or aryl groups. Some examples are given in Figure 1.9.

Figure 1.9 Some examples for amines

### 1.3 IUPAC nomenclature of organic compounds

The set of rules for systematic nomenclature of organic compounds which is now in practice evolved through several international conferences and are known as International Union of Pure and Applied Chemistry rules (IUPAC rules). Therefore, this system of nomenclature is called the IUPAC nomenclature system. In addition to the IUPAC nomenclature many common organic compounds are known by trivial (non-systematic) names. Some examples are given at the end of this section.

### 1.3.1 IUPAC nomenclature

The IUPAC nomenclature system is governed by a large number of rules. In our discussion we will limit ourselves to understand the most important ones which can be used to name more common types of organic compounds. The most important feature of the IUPAC system would be that it will allow us to give one name to a given organic compound and to write only one structure for a given IUPAC name.

In this system, all the compounds with heteroatoms such as $\mathrm{O}, \mathrm{N}$, halogen, are considered to be derived from the corresponding hydrocarbon. Therefore, as a start, let us look at how hydrocarbons are named according to the IUPAC system of nomenclature.

### 1.3.2 Alkane hydrocarbons

All the names of saturated hydrocarbons end with the suffix -ane. The stem of the hydrocarbon name denotes the number of carbon atoms present in the longest carbon chain. Learning the stems is like learning to count in Organic Chemistry. Stem names up to 6 carbon atoms are given in Table 1.3.

Table 1.3 Stem names of hydrocarbons having up to six carbon atoms

| Carbon Number | Stem name | Name of <br> hydrocarbon | Structure |
| :--- | :--- | :--- | :--- |
| 1 | meth- | methane | $\mathrm{CH}_{4}$ |
| 2 | eth- | ethane | $\mathrm{CH}_{3} \mathrm{CH}_{3}$ |
| 3 | prop- | propane | $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{3}$ |
| 4 | but- | butane | $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3}$ |
| 5 | pent- | pentane | $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3}$ |
| 6 | hex- | hexane | $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3}$ |

Before we consider little more complex hydrocarbons, let us look at how we can name alkyl groups.

When we formally remove a H atom from an alkane an alkyl group is obtained. The name of an alkyl group ends with the suffix $\mathbf{- y l}$. When the terminal H atom of an unbranched hydrocarbon is removed the unbranched alkyl group is formed. Some examples are given in Table 1.4.

Table 1.4 Some examples of alkyl groups

| Hydrocarbon | Alkyl group |  |  |
| :--- | :--- | :--- | :--- |
| $\mathrm{H}-\mathrm{CH}_{3}$ | methane | $-\mathrm{CH}_{3}$ | methyl |
| $\mathrm{H}-\mathrm{CH}_{2} \mathrm{CH}_{3}$ | ethane | $-\mathrm{CH}_{2} \mathrm{CH}_{3}$ | ethyl |
| $\mathrm{H}-\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3}$ | propane | $-\mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3}$ | propyl |

### 1.3.3 Nomenclature of branched chain alkanes

Branched chain alkanes can be considered the hydrocarbons which have alkyl groups attached to its longest carbon chain. Let us go through the steps involved in naming of branched chain alkanes taking the following examples.

(1)

(2)

Step 1. Identify the longest continuous chain of carbon atoms and derive the hydrocarbon name.

Note: A methyl group is attached to one of the C atoms of compound 1 and an ethyl group is attached to one of the C atoms of compound 2. A group that replaces an $H$ atom of the hydrocarbon chain is called a substituent group. Therefore methyl group in compound 1 and ethyl group in compound 2 are substituents.

Step 2. Number the carbon atoms of the longest continuous carbon chain such that the C atom bearing the substituent group gets the lowest possible number.

(1)

(2)

Note: The carbon chain of compound lis numbered from right to left. If the carbon chain of this compound is numbered from left to right, the carbon atom to which the methyl group is attached will be assigned number 4 which is a higher number than 2 .

Step 3. Use the number obtained by applying the above step (2) to designate the location of the substituent. Write the name of the compound by placing the hydrocarbon name (name of the parent hydrocarbon) at last preceded by the substituent group with the number designating its location. Numbers are separated from words by a hyphen while numbers are separated by commas.

(1)

2-methylpentane

(2)

3-ethylhexane

When two or more substituents are present they should get the lowest possible numbers designating their location on the longest carbon chain. The substituent groups should be placed alphabetically in the IUPAC name. Let us take two more examples.

|  | ${ }^{1} \mathrm{CH}_{3}{ }^{2} \mathrm{CH}^{2}{ }^{3} \mathrm{H}_{2}{ }_{2}^{4} \mathrm{CH}^{5} \mathrm{CH}_{2}{ }^{6} \mathrm{CH}_{3}$ $\mathrm{CH}_{3} \quad \mathrm{CH}_{2} \mathrm{CH}_{3}$ | $\begin{gathered} \mathrm{CH}_{2} \mathrm{CH}_{3} \\ { }^{1} \mathrm{CH}_{3}^{2} \mathrm{CH}_{2}^{3} \mathrm{C}_{2}^{4} \mathrm{CH}_{2} \mathrm{CH}_{3} \\ \mathrm{CH}_{3} \end{gathered}$ |
| :---: | :---: | :---: |
| Longest hydrocarbon chain | Six - hexane | Five - pentane |
| Substituents and their location | 2-methyl, 4-ethyl | 3-methyl, 3-ethyl |
| IUPAC name | 4-ethyl-2-methylhexane | 3-ethyl-3-methylpentane |

When two or more substituents are identical, they are indicated by the prefixes, di- (2), tri(3), tetra- (4) etc. Every substituent should be given the number that shows its location on the longest carbon chain.

|  | ${ }^{1} \mathrm{CH}_{3}{ }^{2} \mathrm{CH}^{3}{ }^{3} \mathrm{C}_{2}{ }^{4}{ }^{\mathrm{C}} \mathrm{H}^{5} \mathrm{CH}_{3}$ <br> $\stackrel{\mathrm{CH}}{3}^{\mathrm{C}_{3}}$ | $\underset{{ }^{1} \mathrm{CH}_{3}^{2} \mathrm{CH}_{2} \mathrm{CH}_{2}^{34} \mathrm{CH}_{3} \mathrm{CH}_{3}^{5} \mathrm{CH}_{2} \mathrm{CH}_{3}}{ }$ |
| :---: | :---: | :---: |
| Longest hydrocarbon chain | Five - pentane | Six - hexane |
| Substituents and their location | 2-methyl, 4-methyl | 3-methyl, 3-methyl |
| IUPAC name | 2,4-dimethylpentane | 3,3-dimethylhexane |

### 1.3.4 Nomenclature of alkene and alkyne hydrocarbons

Alkenes contain carbon-carbon double bonds. According to IUPAC nomenclature, the suffix -ane is replaced by suffix -ene in alkenes with the number designating the location of the double bond in the parent hydrocarbon. Let us go through the steps involved in naming alkenes taking some examples.

$$
\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}=\mathrm{CH}_{2}
$$

(3)
$\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}=\mathrm{CHCH}_{3}$
(4)

Step 1. Identify the longest continuous carbon chain including the carbon-carbon double bond. Number the carbon chain such that the double bond carbons get the lowest possible numbers.

(3)

(4)

Step 2. Build the IUPAC name by placing the name representing the carbon number and suffix -ene with the lowest number designated to the location of the double bond.

|  | $\stackrel{4}{\mathrm{C}} \mathrm{H}_{3} \stackrel{3}{\mathrm{C}} \mathrm{H}_{2} \stackrel{2}{\mathrm{C}} \mathrm{H}=\stackrel{1}{\mathrm{C}} \mathrm{H}_{2}$ <br> (3) | $\stackrel{5}{\mathrm{C}} \mathrm{H}_{3} \stackrel{4}{\mathrm{C}} \mathrm{H}_{2} \stackrel{3}{\mathrm{C}} \mathrm{H}=\stackrel{2}{\mathrm{C}} \mathrm{H}^{-1} \mathrm{H}_{3}$ <br> (4) |
| :---: | :---: | :---: |
| Longest carbon chain | Four - but | Five - pent |
| Double bond location | 1,2 | 2,3 |
| IUPAC name | but-1-ene (1-butene) | pent-2-ene (2-pentene) |

Step 3. When substituents are present, they are placed in as prefixes along with the number designated to indicate their location in the longest carbon chain containing the double bond.

|  | $\begin{gathered} \stackrel{5}{\mathrm{C}} \mathrm{H}_{3} \stackrel{4}{\mathrm{C}} \mathrm{H} \mathrm{H}_{3}^{3} \mathrm{H}=\stackrel{2}{\mathrm{C}} \mathrm{C} \mathrm{H} \stackrel{1}{\mathrm{C}} \mathrm{H}_{3} \\ \hline \end{gathered}$ |  $\mathrm{CH}_{3} \quad \mathrm{CH}_{3}$ |
| :---: | :---: | :---: |
| Longest carbon chain | Five - pent | Six - hex |
| Double bond location | 2,3 | 2,3 |
| Parent hydrocarbon name | pent-2-ene (2-pentene) | hex-2-ene (2-hexene) |
| Substituents with location | 4-methyl | 3-methyl, 5-methyl |
| IUPAC name | 4-methylpent-2-ene <br> (4-methyl-2-pentene) | 3,5-dimethylhex-2-ene (3,5-dimethyl-2-hexene) |

If the double bond gets the same set of numbers when the chain is numbered from either sides of the carbon chain, then the numbering should be done such that substituents get the lowest possible numbers.

|  |  |  |
| :---: | :---: | :---: |
| Longest carbon chain | Six - hex | Six - hex |
| Double bond location | 3, 4 | 3, 4 |
| Parent hydrocarbon name | hex-3-ene (3-hexene) | hex-3-ene (3-hexene) |
| Substituents with location | 2-methyl | 2-methyl, 4-methyl |
| IUPAC name | 2-methylhex-3-ene (2-methyl-3-hexene) | 2,4-dimethylhex-3-ene <br> (2,4-dimethyl-3-hexene) |

Alkynes contain carbon-carbon triple bonds. They are named by replacing suffix -ane of alkane by suffix -yne. The rest follows similar to nomenclature of alkenes.

|  |  |  |
| :---: | :---: | :---: |
| Longest carbon chain | Five - pent | Six - hex |
| Triple bond location | 2, 3 | 3, 4 |
| Parent hydrocarbon name | pent-2-yne (2-pentyne) | hex-3-yne (3-hexyne) |
| Substituents with location | 4-methyl | 2-methyl |
| IUPAC name | 4-methylpent-2-yne <br> (4-methyl-2-pentyne) | 2-methylhex-3-yne (2-methyl-3-hexyne) |

Let us now summarize the basic principles of naming hydrocarbons according to the IUPAC system. This will be the foundation for the naming of compounds containing functional groups.
(i) All the compounds are considered to be derived from the hydrocarbon containing the longest carbon chain.
(ii) When a double bond or a triple bond is present, the longest carbon chain should be chosen to include the double bond or the triple bond.
(iii) A suitable suffix (-ane, -ene or -yne) is added to the stem name which denotes the number of carbon atoms (parent hydrocarbon).
(iv) When double bonds or triple bonds are absent, the carbon atoms carrying substituents are given the lowest possible numbers.
(v) When a double bond or a triple bond is present it is given the lowest possible number.
(vi) Substituent names are placed as prefixes to the parent hydrocarbon name in the alphabetical order.

### 1.3.5 IUPAC nomenclature of compounds other than hydrocarbons

In this section nomenclature of compounds containing other functional groups (Table 1.2) will be discussed. This also follows the principles we have already discussed. In addition we now need a class name (suffix) to designate the functional group present in the molecule.

Let us take class names (suffixes) (Table 1.5) of some functional groups and study how these principles should be applied in naming compounds with one functional group.

Table 1.5 Class names of some functional groups

| Functional group | Name of the homologous series | Class name (Suffix) |
| :---: | :---: | :---: |
| - OH | Alcohol | -ol |
|  | Aldehyde | -al |
| $-c^{\prime \prime}$ | Ketone | -one |
|  | Carboxylic acid | -oic acid |

Let us now go through the steps involved in naming the following compounds.

$$
\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{OH}
$$

1. Identify the longest continuous carbon chain containing the functional group and number the carbon atoms of the carbon chain such that the C atom bearing the functional group gets the lowest possible number.

2. Derive the parent hydrocarbon name which shows the number of C atoms and whether it is saturated or contains a double bond or a triple bond.

| ${ }^{4} \mathrm{H}_{3}{ }^{3} \mathrm{H}_{2}{ }^{2} \mathrm{H}_{2} \mathrm{C}_{\mathrm{C}} \mathrm{H}_{2} \mathrm{OH}$ |  | ${ }^{5} \mathrm{CH}_{3}{ }^{4} \mathrm{CH}_{2}{ }^{3}{ }^{\mathrm{C}} \mathrm{H}_{2}{ }^{\mathrm{O} \mathrm{CH}} \mathrm{CH}^{1} \mathrm{CH}_{3}$ |  | ${ }^{5} \mathrm{CH}_{3}^{4} \mathrm{CH}_{2}^{3} \mathrm{CH}_{2}{ }_{2}^{\mathrm{O} \mathrm{CCH}_{3}^{1}}$ |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 4 C atoms: | but | 5 C atoms: | pent | 5 C atoms: | pent |
| Saturated hydrocarbon chain: | ane | Saturated hydrocarbon chain: | ane | Saturated hydrocarbon chain: | ane |
| but + ane; butane |  | pent + ane; <br> pentane |  | pent + ane; <br> pentane |  |

3. Write the name of the compound by placing the hydrocarbon name deleting the last letter 'e' (name of the parent hydrocarbon) followed by the suffix identifying the functional group with the number designating its location.

## G.C.E. (A/L) CHEMISTRY: UNIT 7 Basic Concepts of Organic Chemistry

<br>butane + 1-ol butan-1-ol (1-butanol)

<br>pentane +2 -ol<br>pentan-2-ol (2-pentanol)

pentane +2 -one
pentan-2-one (2-pentanone)

The IUPAC names derived above give the following information:
(i) The number of C atoms in the longest continuous carbon chain (pent, but etc.).
(ii) The saturated nature of the carbon chain (-an-)
(iii) The functional group present in the molecule and its position (1-ol, 2-ol or 2-one).

Note:The hydroxyl group $(\mathrm{OH})$ of alcohols can be positioned on any carbon atom including the terminal carbon atom of the carbon chain while the carbonyl group $(C=O)$ of ketones cannot be positioned at the terminal carbon atom of the carbon chain. Thus in naming alcohols and ketones the number designating the location of the functional group has to be stated.

The carbonyl group $(\mathrm{C}=\mathrm{O})$ of the aldehydes and the carboxylic acids are always positioned at the terminal carbon atom of the carbon chain. Therefore it is not necessary to state the number designating their location.

Let us take the following two examples.

$$
\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{COOH}
$$

$$
\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CHO}
$$

1. Identify the longest continuous carbon chain containing the functional group and number the carbon atoms of the carbon chain such that the C atom of the functional group gets number 1 .

2. Derive the parent hydrocarbon name which shows the number of C atoms and whether it is saturated or contains a double bond or a triple bond.

$$
\begin{array}{ll}
\stackrel{4}{\mathrm{CH}_{3}}{ }_{3}^{3} \mathrm{CH}_{2}{ }^{2} \mathrm{CH}_{2}{ }^{1} \mathrm{COOH} & { }_{5}^{5} \mathrm{CH}_{3}{ }^{4} \mathrm{CH}_{2} \stackrel{3}{\mathrm{C}} \mathrm{H}_{2}{ }^{2} \mathrm{CH}_{2}{ }^{1} \mathrm{CHO} \\
4 \mathrm{C} \text { atoms and saturated } & 5 \mathrm{C} \text { atoms and saturated } \\
\text { hydrocarbon (but }+ \text { ane) } & \text { hydrocarbon (pent }+ \text { ane) }
\end{array}
$$

3. Write the name of the compound by placing the hydrocarbon name deleting the last letter 'e' (name of the parent hydrocarbon) followed by the suffix identifying the functional group. Because aldehyde functional group and carboxylic acid functional group always get number 1, the number is not stated in the name.

## G.C.E. (A/L) CHEMISTRY: UNIT 7 Basic Concepts of Organic Chemistry

<br>butane + oic acid<br>butanoic acid

pentanal

Let us now take few examples containing alkyl substituents attached to the longest continuous carbon chain. Recall that aldehyde and carboxylic acid functional groups are always positioned at the terminal of the carbon chain. Hence the C of these two functional groups is given number 1 when numbering.

Let us go through the steps involved in naming the above examples.

1. Identify the longest continuous carbon chain containing the functional group and number the carbon atoms of the carbon chain such that the C atom of the functional group gets number 1 .

2. Derive the parent hydrocarbon name which shows the number of C atoms and whether it is saturated or contains a double bond or a triple bond.

4 C atoms and saturated hydrocarbon (but + ane)

6 C atoms and saturated hydrocarbon (hex+ ane)
3. Identify the substituent groups with the location.

3-methyl

4-methyl
4. Build the IUPAC name of the compound by placing the hydrocarbon name deleting the last letter ' $e$ ' (name of the parent hydrocarbon) followed by the suffix identifying the functional group. Place the substituent names with their locations as prefixes. When there are several substituents they should be placed in the alphabetical order.

```
\(\mathrm{CH}_{3}\)
3-methyl+butane+al
3-methylbutanal
```

4-methyl+hexane+oic acid
4-methylhexanoic acid

Let us take two more examples.

|  |  | $\begin{gathered} { }^{6} \mathrm{CH}_{3}{\stackrel{5}{\mathrm{C}} \mathrm{H}_{2}{ }_{2}^{4} \mathrm{CH}^{3} \mathrm{CH}_{2} \mathrm{CH}_{2}^{\mathrm{C}} \mathrm{CH}_{3} \mathrm{CH}_{3} \mathrm{COOH}}^{2} \end{gathered}$ |
| :---: | :---: | :---: |
| Longest carbon chain | 5C-pent | 6C - hex |
| Parent hydrocarbon name | pentane | hexane |
| Functional group (with location) | 1-al | 1 -oic acid |
| Substituents with locations | 2-methyl, 4-methyl | 2-methyl, 4-ethyl |
| IUPAC name | 2,4-dimethylpentanal | 4-ethyl-2-methylhexanoic acid |

Carbon chains of compounds containing functional groups that can be placed on any carbon atom (such as alcohols and ketones) should be numbered such that the functional group gets the lowest possible number. Rest of the steps discussed will then be followed to build the IUPAC name.

Let us take few examples.

|  | $\begin{gathered} \stackrel{5}{\mathrm{C}} \mathrm{H}_{3} \stackrel{4}{\mathrm{C}} \stackrel{\mathrm{CH}}{3}^{\mathbf{C}} \mathrm{H}_{2} \stackrel{2}{\mathrm{C}} \stackrel{+}{\mathrm{C}} \mathrm{H}_{3} \mathrm{C}_{2} \mathrm{H}_{2} \mathrm{OH} \\ \hline \end{gathered}$ | $\begin{array}{cc} { }_{5}^{5} & \begin{array}{c} \mathrm{OH} \\ \mathrm{CH}_{3} \mathrm{CH}^{2} \mathrm{CH}_{2} \mathrm{CCH}_{3} \\ \mathrm{CH}_{3} \\ \mathrm{CH}_{3} \end{array} \end{array}$ |
| :---: | :---: | :---: |
| Longest carbon chain | 5 C atoms - pent | 5C atoms - pent |
| Parent hydrocarbon name | pentane | pentane |
| Functional group (with location) | OH at C-1 (1-ol) | OH at C-2 (2-ol) |
| Substituents with locations | 2-methyl, 4-methyl | 2-methyl, 4-methyl |
| IUPAC name | 2,4-dimethylpentan-1-ol <br> 2,4-dimethy- lpentanol | 2,4-dimethylpentan-2-ol <br> 2,4-dimethyl-2-pentanol |
|  | $\begin{gathered} \mathrm{OHCH}_{3}{ }^{6} \mathrm{CH}_{3}{ }^{5} \mathrm{CH}_{2}^{4} \mathrm{CH}^{3} \mathrm{C}-\mathrm{CH}_{3}^{1} \mathrm{CH}_{3} \\ \mathrm{CH}_{2} \mathrm{CH}_{3} \end{gathered}$ | $\begin{gathered} \mathrm{O} \\ \mathrm{CH}_{3}^{211 \mathrm{C}^{3}} \mathrm{CHCH}_{3} \\ \mathrm{CH}_{3}^{+} \mathrm{CH}^{+} \mathrm{H}^{5} \mathrm{CH}_{3} \end{gathered}$ |
| Longest carbon chain | 6C atoms - hex | 5C atoms - pent |
| Parent hydrocarbon name | hexane | pentane |
| Functional group (with location) | $\mathrm{C}=\mathrm{O}$ at $\mathrm{C}-3$ (3-one) | $\mathrm{C}=\mathrm{O}$ at C-2 (2-one) |
| Substituents with locations | 2-methyl, 4-ethyl | 3-methyl, 4-methyl |
| IUPAC name | 4-ethyl-2-methylhexan-3-one 4-ethyl-2-methyl-3-hexanone | 3,4-dimethylpentan-2-one <br> 3,4-dimethyl-2-pentanone |

When the compound contains a double bond or a triple bond (a multiple bond), the longest chain must contain both the functional group and the multiple bond. Accordingly the parent hydrocarbon will be either an alkene or an alkyne. Rest of the steps discussed will then be followed to build the IUPAC name. Let us take a look at few examples.

|  |  |  |
| :---: | :---: | :---: |
| Longest carbon chain | 5C atoms - pent | 4C atoms - but |
| Functional group with location | oic acid | 2-ol |
| Double/triple bond with location | 3-ene | 3-ene |
| Parent hydrocarbon name | pent-3-ene | but-3-ene |
| Substituents with locations | 2-methyl, 4-methyl | 3-ethyl |
| IUPAC name | 2,4-dimethylpent-3-enoic acid 2,4-dimethyl-3-pentenoic acid | $\begin{aligned} & \text { 3-ethylbut-3-en-2-ol } \\ & \text { 3-ethyl-3-buten-2-ol } \end{aligned}$ |

|  | $\begin{gathered} { }^{6} \mathrm{CH}_{3}^{5} \\ \mathrm{CH}_{3} \mathrm{C}=\mathrm{C}^{4} \mathrm{CH}^{3} \mathrm{CH}^{1} \mathrm{CCH}_{3} \\ \mathrm{CH}_{3} \\ \mathrm{O} \end{gathered}$ | ${ }_{\mathrm{C}}^{\mathrm{C}} \mathrm{H}_{3}{ }^{5} \mathrm{C}={ }_{4} \mathrm{C}^{\mathrm{C} \mathrm{CH}_{3}} \mathrm{H}^{2} \mathrm{CH}_{2}^{1} \mathrm{CHO}$ |
| :---: | :---: | :---: |
| Longest carbon chain | 6 C atoms - hex | 6C atoms - hex |
| Functional group with location | 2-one | al |
| Double/triple bond with location | 4-ene | 4-yne |
| Parent hydrocarbon name | hex-4-ene | hex-4-yne |
| Substituents with locations | 3-methyl, 5-methyl | 3-methyl |
| IUPAC name | 3,5-dimethylhex-4-en-2-one | 3-methylhex-4-ynal |
|  | 3,5-dimethyl-4-hexen-2-one | 3-methyl-4-hexynal |

### 1.3.6 IUPAC nomenclature of compounds containing more than one functional group

There are many organic compounds containing several functional groups. Recall that in the foregoing discussion you learnt that compounds are named according to their functional group. In the IUPAC nomenclature system, functional groups are arranged in a priority order. When there are two functional groups in a molecule, the compound is named according to the functional group that gets the highest priority. The functional group with the highest priority is called the principal functional group. The remaining functional group is considered as a
substituent. When a functional group is considered as substituent, it is given a different name to be used as a prefix. The carbon chain is numbered so that the principal functional group gets the lowest possible number. Class names and substituent names of some functional groups are given in Table 1.6 in the order of their priority.

Table 1.6 Class names and substituent names of some functional groups in their priority order

| Functional group | Name of the homologous <br> series | Substituent name <br> (prefix) | Class name (suffix) |
| :--- | :--- | :--- | :--- |
| -COOH | Carboxylic acid | - | oic acid |
| -COOR | Acid chloride | - | oate |
| -COCl | Amide | - | oyl chloride |
| $-\mathrm{CONH}_{2}$ | Nitrile | - | amide |
| -CN | Aldehyde | cyano | nitrile |
| -CHO | Ketone | oxo | al |
| $-\mathrm{CO}-$ | Alcohol | hydroxy- | one |
| -OH | Amine | amino | amine |
| -NH | fluoro- | - |  |
| -F |  | chloro- | - |
| -Cl | bromo- | - |  |
| -Br |  | odo- | - |
| -I | nitro | - |  |
| $-\mathrm{NO}_{2}$ |  |  |  |

Note: alkene $(C=C)$ as "ene" and alkyne $(C \equiv C)$ as "yne" are used as suffixes.

|  |  |
| :--- | :--- |
| Longest carbon chain | 5C atoms - pent |
| Functional group with highest <br> priority and its location | oic acid |
| Double/triple bond with <br> location | 3-ene |
| Parent hydrocarbon name | pent-3-ene |
| Substituents with locations | 2-hydroxy, 2-methyl, 4-methyl |
| IUPAC name | 2-hydroxy-2,4-dimethylpent-3-enoic acid <br> 2-hydroxy-2,4-dimethyl-3-pentenoic acid |

|  |  |
| :---: | :---: |
| Longest carbon chain | 6C atoms - hex |
| Functional group with highest priority and its location | 3-one |
| Double/triple bond with location | none |
| Parent hydrocarbon name | hexane |
| Substituents with locations | 2-hydroxy, 5,5-dimethyl |
| IUPAC name | 2-hydroxy-5,5-dimethylhexan-3-one 2-hydroxy-5,5-dimethyl-3-hexanone |

|  |  |
| :---: | :---: |
| Longest carbon chain | 6C atoms - hex |
| Functional group with highest priority and its location | oic acid |
| Double/triple bond with location | 4-ene |
| Parent hydrocarbon name | hex-4-ene (4-hexene) |
| Substituents with locations | 3-oxo, 2-methyl, 5-methyl |
| IUPAC name | 2,5-dimethyl-3-oxohex-4-enoic acid 2,5-dimethyl-3-oxo-4-hexenoic acid |

|  | $\underset{\substack{\mathrm{CH}_{3} \\{ }^{6} \mathrm{CH} \mathrm{CH}_{3}^{51} \mathrm{C}=\mathrm{CH}^{3} \mathrm{C} \mathrm{CH}^{2} \mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CHH}_{2} \\ \mathrm{OH}}}{ }$ |
| :---: | :---: |
| Longest carbon chain | 6C atoms - hex |
| Functional group with highest priority and its location | 3 -ol |
| Double/triple bond with location | 4-ene |
| Parent hydrocarbon name | hex-4-ene (4-hexene) |
| Substituents with locations | 1-amino, 2,5-dimethyl |
| IUPAC name | 1-amino-2,5-dimethylhex-4-en-3-ol 1-amino-2,5-dimethyl-4-hexen-3-ol |

|  |  |
| :---: | :---: |
| Functional group with highest priority and its location | 5C atoms - pent |
|  | 3-one (when numbered from either side) In such a case, the direction of numbering is chosen so as to give the lowest possible numbers to the substituent groups. |
| Parent hydrocarbon name | pentane |
| Substituents with locations | 1-hydroxy, 4-methyl |
| IUPAC name | 1-hydroxy-4-methylpentan-3-one 1-hydroxy-4-methyl-3-pentanone |
|  | $\stackrel{\mathrm{OH}}{\mathrm{CH}_{2}=\mathrm{CH}^{3} \mathrm{CH}^{4} \mathrm{CH}_{2}^{5} \mathrm{CH}_{3}}$ |
| Longest carbon chain | 5C atoms - pent |
| Functional group with highest priority and its location | 3-ol (when numbered from either side) In this case, we should give the lowest possible number to the double bond. |
| Double/triple bond with location | 1-ene |
| Parent hydrocarbon name | pent-1-ene (1-pentene) |
| Substituents with locations | none |
| IUPAC name | $\begin{aligned} & \text { pent-1-en-3-ol } \\ & \text { 1-penten-3-ol } \\ & \hline \end{aligned}$ |
|  |  |
| Longest carbon chain 5C atoms - pent |  |
| Functional group with <br> highest priority and its <br> location 3-one (whe <br> number sho <br> substituted | mbered from either side). The lowest possible be given to the double bond. Recall how the ne and alkynes were named. |
| Double/triple bond with 1 -ene location |  |
| Parent hydrocarbon name pent-1-ene (1-pentene) |  |
| Substituents with locations 5-hydroxy, 2,4-dimethyl |  |
| IUPAC name | dimethylpent-1-en-3-one dimethyl-1-penten-3-one |

|  | $\begin{gathered} \mathrm{OCH}_{3} \\ \mathrm{CH}_{2}=\mathrm{CO}_{3}^{3} \mathrm{C}^{3}-\mathrm{C}^{4}-\mathrm{CH}^{2} \mathrm{CH}_{2} \mathrm{OH} \\ \mathrm{CH}_{2} \mathrm{CH}_{3} \end{gathered}$ |
| :---: | :---: |
| Longest carbon chain | 5 C atoms - pent (not hex; the carbon chain should include the $\mathrm{C}=\mathrm{C}$ ). |
| Functional group with highest priority and its location | 3-one |
| Double/triple bond with location | 1-ene |
| Parent hydrocarbon name | pent-1-ene (1-pentene) |
| Substituents with locations | 5-hydroxy, 2-ethyl, 4-methyl |
| IUPAC name | 2-ethyl-5-hydroxy-4-methylpent-1-en-3-one 2-ethyl-5-hydroxy-4-methyl-1-penten-3-one |

Let us now summarize the stepwise approach to build the IUPAC name of a compound (other than hydrocarbons).

1. Identify the longest hydrocarbon chain which includes the functional group having the highest priority (principal functional group) (Table 1.6) and any double or triple bonds.
2. Number the hydrocarbon chain:
a. Such that the principal functional group gets the lowest possible number.
b. If the principal functional group gets the same number when the hydrocarbon chain is numbered from different directions, then the direction giving the lowest possible number to the multiple bond is chosen.
c. If the principal functional group gets the same number when the hydrocarbon chain is numbered from different directions and multiple bonds are absent, then the direction giving the lowest possible numbers to the substituents is chosen.
3. Derive the hydrocarbon name using the name designated for the number of C atoms and suffix for the saturation or unsaturation with its position number (ane, ene or yne).
4. Add the suffix designating the principal functional group.
5. Add prefixes designating the substituent groups along with their position numbers.
6. Then build the IUPAC name as follows:

| Prefix | + Hydrocarbon name | +Suffix <br> Substituent groups <br> with position <br> numbersNumber of C atoms and <br> suffix for the saturation <br> or unsaturation with its <br> position number |
| :---: | :---: | :---: | | Class name of the |
| :---: |
| principal functional |
| group |

## Trivial Names

Prior to the development of systematic nomenclature organic compound were known by trivial (common) names. As the trivial names of common compounds are still used by chemists it is advisable to be familiar with these names. Trivial names of some common compounds and their corresponding IUPAC names are given in Table 1.7.

Table 1.7 Trivial names of some common compounds and their IUPAC names.

| Compound | Trivial name | IUPAC name |
| :--- | :--- | :--- |
| $\mathrm{CH}_{3} \mathrm{COOH}$ | acetic acid | ethanoic acid |
| $\mathrm{CH}_{3} \mathrm{CHO}$ | acetaldehyde | ethanal |
| $\mathrm{CH}_{3} \mathrm{COCH}_{3}$ | acetone | propanone |
| $\mathrm{CH}_{3} \mathrm{CN}$ | acetonitrile | ethanenitrile |
| $\mathrm{HC} \equiv \mathrm{CH}$ | acetylene | ethyne |
| $\mathrm{CHCl}_{3}$ | chloroform | trichloromethane |
| $\mathrm{HOCH}_{2} \mathrm{CH}_{2} \mathrm{OH}$ | ethylene glycol | ethane-1,2-diol |
| $\mathrm{HCHO}_{\mathrm{HCOOH}}$ | formaldehyde | methanal |

### 1.4 Isomerism

Isomerism is the existence of different compounds that have the same molecular formula. Different compounds having the same molecular formula are called isomers. Isomers can be subdivided into constitutional isomers and stereoisomers.

### 1.4.1 Constitutional (structural) isomerism

Isomers that differ from the order in which the constituent atoms are connected to each other are called constitutional isomers. Hence they have different structural formulae. A few examples of constitutional isomers are shown in Table 1.8.

Table 1.8 Some examples of constitutional isomers

| Molecular formula | Constitutional isomers |  |  |
| :---: | :---: | :---: | :---: |
| $\mathrm{C}_{5} \mathrm{H}_{12}$ | $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3}$ | $\underset{\substack{\mathrm{CH}_{3} \mathrm{CH}_{3} \\ \mathrm{CH} \mathrm{CH}_{2} \mathrm{CH}_{3}}}{\text { ( }}$ |  |
| $\mathrm{C}_{3} \mathrm{H}_{8} \mathrm{O}$ | $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{OH}$ |  | $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OCH}_{3}$ |
| $\mathrm{C}_{4} \mathrm{H}_{8} \mathrm{O}$ | $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \stackrel{\mathrm{H}}{\mathrm{H}}=\mathrm{O}$ |  |  |

Constitutional isomers are generally subdivided into chain isomers, position isomers and functional group isomers. These subdivisions are not exclusive and can overlap.

Chain isomers: Chain isomers are those which have different hydrocarbon chains for same molecular formula (Figure 1.10).

Figure 1.10 Chain isomers for the molecular formula $\mathrm{C}_{5} \mathrm{H}_{12} \mathrm{O}$
Position isomers: Position isomers are those which have the same functional group and/or substituents in different positions in the same carbon chain (Figure 1.11).

Figure 1.11 Examples of position isomers
Functional group isomers: Functional group isomers are those which have different functional groups in compounds having the same molecular formula (Figure 1.12).

Figure 1.12 Examples of functional group isomers
Chain isomerism, position isomerism and functional group isomerism can overlap. Take a look at the isomers which have been drawn for the molecular formula $\mathrm{C}_{4} \mathrm{H}_{8} \mathrm{O}$ (Figure 1.13).

Figure 1.13 Constitutional isomers for the molecular formula $\mathrm{C}_{4} \mathrm{H}_{8} \mathrm{O}$

### 1.4.2 Stereoisomerism

Stereoisomerism is the existence of compounds whose structures differ from each other only in the orientation of bonds in three-dimensional space. Stereoisomers have the same structural formulae. They have the same connectivity: their constituent atoms are connected in the same order but differ in the manner in which atoms or groups are arranged in three-dimensional space. Therefore their structures cannot be superimposed on each other even though they have the same molecular and structural formulae. Pair of stereoisomers whose three-dimensional structures are mirror images of each other are enantiomers of each other. Pairs of stereoisomers whose three-dimensional structures are not mirror images of each other are diastereomers of each other.

The different types of isomers described above and their classification is shown in Figure 1.14.

Figure 1.14 Classification of isomers

## Diastereomerism

Geometric isomerism is one occasion where diastereomerism is seen. A $\mathrm{C}=\mathrm{C}$ double bond consists of a $\sigma$-bond and a $\pi$-bond. Due to the $\pi$ bond, the two carbon atoms cannot freely rotate about the $\sigma$-bond. Both alkene carbon atoms and the four atoms attached to them are all in one plane. For geometrical isomers to exist, the two groups attached to each carbon atom of the double bond should not be identical. In such an instance it is possible to have two compounds which differ from each other in the spatial arrangements of the groups joined to the two carbon atoms. These two compounds cannot be superimposed on each other and cannot interconvert by rotation around the carbon-carbon bond axis (due to the $\pi$-bond). Such compounds are known as geometrical isomers.

For example,

are diastereoisomers because the structures cannot be superimposed on each other.

However,

are the same because the structures can be superimposed on each other.

## Cis and trans nomenclature

In alkenes the words cis and trans are used to indicate the geometrical relationship of two groups attached to different carbon atoms in the same double bond. Consider a plane passing through the $\mathrm{C}=\mathrm{C}$ which is perpendicular to the plane of the molecule (See Figure 1.15). If the two groups are on the same side of this plane, then the relationship is cis. Observe that in Figure $\mathbf{1 . 1 5}$ the two H -atoms are cis to each other and the two methyls are also cis to each other.

Figure 1.15 cis-2-butene showing the plane perpendicular to the plane of the molecule
If the two groups are on opposite sides of the plane then the relationship is trans. Observe that H atom on $\mathrm{C}_{\mathrm{a}}$ is trans to the methyl group on $\mathrm{C}_{\mathrm{b}}$ (see Figure 1.16).

Note that the geometrical isomer of cis-2-butene is trans-2-butene in which the two methyl groups are trans to each other (the two H atoms are also trans to each other).

Figure 1.16 trans-2-butene

## Enantiomerism

Isomers which are mirror images of each other are known as enantiomers (see Figure 1.17). A compound having a carbon atom which is joined to four different groups shows enantiomerism. Such a carbon atom is known as an asymmetric or chiral carbon atom. When plane polarized light is passed through a solution containing only one enantiomer, the plane of polarization rotates.

One enantiomer rotates the plane of polarization in one direction and the other enantiomer in the opposite direction. As the enantiomers rotate the plane of polarization, they are also known as optical isomers. Compounds which rotate the plane of plane polarized light are known as optically active compounds.

Figure 1.17 Enantiomers of bromochlorofluoromethane
Observe that the above mirror images of each other are not superimposable.
Note: Stereoisomers which are not mirror images of each other are known as diastereomers. Therefore geometrical isomers are diastereomers.

## 2. Hydrocarbons \& Halohydrocarbons

## Content

2.1 Structure, physical properties and nature of bonds of aliphatic hydrocarbons
2.1.1 Properties of alkanes
2.1.2 Structure of alkanes
2.1.3 Properties of alkenes and alkynes
2.1.4 Structure of alkenes
2.1.5 Structure of alkynes
2.2 Chemical reactions of alkanes, alkenes and alkynes in terms of their structures
2.2.1 Reactions of alkanes
2.2.1.1 Chlorination of alkanes
2.2.2 Reactions of alkenes
2.2.2.1 Addition of hydrogen halides $(\mathrm{HCl}$, HBr or HI$)$
2.2.2.2 Addition of bromine to alkenes
2.2.2.3 Addition of sulphuric acid and the hydrolysis of the addition product
2.2.2.4 Catalytic addition of hydrogen (Hydrogenation)
2.2.2.5 Reaction of alkenes with cold, alkaline, dilute potassium permanganate
2.2.3 Reactions of alkynes
2.2.3.1 Addition of bromine
2.2.3.2 Addition of hydrogen halides
2.2.3.3 Addition of water
2.2.3.4 Catalytic addition of hydrogen (Hydrogenation)
2.2.4 Acidic nature of alkynes with terminal hydrogen
2.3 The nature of bonding in benzene
2.3.1 Structure of benzene
2.3.2 Stability of benzene

## Introduction

Hydrocarbons are compounds containing only carbon and hydrogen. We have already discussed that aliphatic hydrocarbons are classified as alkanes, alkenes and alkynes. Halohydrocarbons are compounds containing one or more halogen atoms in addition to carbon and hydrogen.

### 2.1 Structure, physical properties and nature of bonds of aliphatic hydrocarbons

Alkane hydrocarbons are saturated hydrocarbons. Only carbon-hydrogen and carbon-carbon single bonds are found in these compounds. Methane $\left(\mathrm{CH}_{4}\right)$ is the simplest alkane hydrocarbon and it contains only one carbon atom. There are four hydrogen atoms attached to this carbon atom by four single bonds. The alkane which contains two carbon atoms is ethane $\left(\mathrm{C}_{2} \mathrm{H}_{6}\right)$. In ethane the two carbons are bonded to each other with a single bond and each of these carbon atoms is bonded to three hydrogen atoms. The alkane with three carbon atoms is propane $\left(\mathrm{C}_{3} \mathrm{H}_{8}\right)$. It will be noticed that the formula of ethane differs from that of methane by $\mathrm{CH}_{2}$, and that the formula of propane differs from that of ethane also by $\mathrm{CH}_{2}$. If two consecutive members of a series of compounds differ only by a $\mathrm{CH}_{2}$ unit, such a series of compounds is called a homologous series.

A homologous series is a series of compounds with similar chemical properties which share the same general formula in which consecutive members of a series of compounds differ only by a $\mathrm{CH}_{2}$ unit. The general formula of an alkane is $C_{n} H_{2 n+2}$ (where $n=1,2,3, \ldots$ ) and all alkanes except cyclic alkanes follow this general formula.

### 2.1.1 Properties of alkanes

An alkane molecule is non-polar or very weakly polar. The attractive forces between two nonpolar molecules are the dispersion forces. While the first few members of the series are gases at room temperature, the higher members are liquids and solids. As a result of increase in surface area down the series, dispersion forces also increase. While this leads to the aforesaid variation in the physical states of hydrocarbons, it also results in increase of the boiling points and melting points of unbranched hydrocarbons with the increase in molecular weight (Table 2.1).

Table 2.1 Melting points, boiling points and densities of some straight chain alkanes, showing regular increase of the property with the carbon number

| Name | Formula | Melting point $/{ }^{\circ} \mathrm{C}$ | Boiling point $/{ }^{\circ} \mathrm{C}$ | Density <br> $\left(\right.$ at 20 $\left.{ }^{\circ} \mathrm{C}\right) / \mathbf{g ~ c m}$ <br>  <br> -3 |
| :--- | :--- | :--- | :--- | :--- |
| methane | $\mathrm{CH}_{4}$ | -183 | -162 |  |
| ethane | $\mathrm{CH}_{3} \mathrm{CH}_{3}$ | -172 | -88.5 |  |
| propane | $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{3}$ | -187 | -42 |  |
| butane | $\mathrm{CH}_{3}\left(\mathrm{CH}_{2}\right)_{2} \mathrm{CH}_{3}$ | -138 | -0.5 | 0.626 |
| pentane | $\mathrm{CH}_{3}\left(\mathrm{CH}_{2}\right)_{3} \mathrm{CH}_{3}$ | -130 | 36 |  |

| Name | Formula | Melting point/ ${ }^{\circ} \mathrm{C}$ | Boiling point/ ${ }^{\circ} \mathrm{C}$ | Density <br> $\left(\right.$ at $\left.\mathbf{2 0}{ }^{\circ} \mathbf{C}\right) / \mathbf{g ~ c m}$ <br>  <br> -3 |
| :--- | :--- | :--- | :--- | :--- |
| hexane | $\mathrm{CH}_{3}\left(\mathrm{CH}_{2}\right)_{4} \mathrm{CH}_{3}$ | -95 | 69 | 0.659 |
| heptane | $\mathrm{CH}_{3}\left(\mathrm{CH}_{2}\right)_{5} \mathrm{CH}_{3}$ | -90.5 | 98 | 0.659 |
| octane | $\mathrm{CH}_{3}\left(\mathrm{CH}_{2}\right)_{6} \mathrm{CH}_{3}$ | -57 | 126 | 0.659 |
| nonane | $\mathrm{CH}_{3}\left(\mathrm{CH}_{2}\right)_{7} \mathrm{CH}_{3}$ | -54 | 151 | 0.718 |
| decane | $\mathrm{CH}_{3}\left(\mathrm{CH}_{2}\right)_{8} \mathrm{CH}_{3}$ | -30 | 174 | 0.730 |

With branching of the carbon chain the surface area of a molecules decreases and consequently dispersion forces become weaker and the boiling point decreases. As can be seen from the data given in Table 2.2 the boiling points of alkanes with five carbon atoms decrease with the increase in branching of the carbon chain.

Table 2.2 Reduction of boiling points of isomeric pentanes as the branching occurs

| Compound | Boiling point $/{ }^{\circ} \mathbf{C}$ |
| :--- | :--- |
| pentane | 36 |
| 2-methylbutane | 28 |
| 2,2-dimethylpropane | 9 |

### 2.1.2 Structure of alkanes

Let us consider the bonding of the simplest alkane, methane $\left(\mathrm{CH}_{4}\right)$. The carbon atom forms four covalent bonds with four hydrogen atoms. A covalent bond is formed by the overlap of two orbitals of two different atoms, each of which contains one electron. As the carbon atom in its ground state has only two $p$ orbitals ( $p_{x}$ and $p_{y}$ ) containing one electron each, it could form only two covalent bonds at right angles to each other (recall that electronic configuration of C in its ground state is $1 s^{2} 2 s^{2} 2 p^{2}$ ). If the two electrons in the $2 s$ orbital are unpaired and one electron is promoted to the $p_{z}$ orbital, then the carbon atom would have four orbitals, each containing one electron to form four bonds to four hydrogen atoms. The energy required to unpair and promote an electron could be compensated by the energy released by the formation of two extra bonds.

However, this overlap would result in a $\mathrm{CH}_{4}$ molecule where three of the $\mathrm{C}-\mathrm{H}$ bonds will be at right angles to each other and one C-H bond will not have any directionality. This would lead to a methane molecule which would have two types of $\mathrm{C}-\mathrm{H}$ bonds. In order to explain the fact that in methane all four $\mathrm{C}-\mathrm{H}$ bonds are equivalent, the $2 s$ orbital and the three $2 p$ orbitals are considered to be mixed with each other, to generate four equivalent orbitals pointing to the apices of a tetrahedron (Figure 2.1).

## G.C.E. (A/L) CHEMISTRY: UNIT 8

Figure 2.1 Shape and arrangement of $s p^{3}$ hybrid orbitals of carbon
The mixing of orbitals to generate new orbitals is termed 'hybridization'. The new orbitals are termed hybrid orbitals to differentiate them from pure atomic orbitals. In methane, the four hybrid orbitals of carbon are called $s p^{3}$ hybrid orbitals as one $s$ orbital and three $p$ orbitals are mixed to generate them. Such carbon atoms are referred to as ' $\boldsymbol{s} \boldsymbol{p}^{3}$ hybridized carbon'. The energy of the $s p^{3}$ hybrid orbitals lies between the energy of the $s$ orbital and the $p$ orbitals (Figure 2.2).

Figure 2.2 Graphical representation of hybridization of carbon in methane
In methane each of these four $s p^{3}$ hybridized orbitals overlap with $s$ orbital of H atoms and forms four $\mathrm{C}-\mathrm{H}$ bonds. The angle between any of these two $\mathrm{C}-\mathrm{H}$ bonds is $109.5^{\circ}$ and the four H atoms of methane are located at the apices of a tetrahedron (Figure 2.3).

Figure 2.3 Tetrahedral shape of methane $\left(\mathrm{CH}_{4}\right)$ molecule
All carbon atoms joined to four other atoms in any organic compound are considered $s p^{3}$ hybridized. In alkanes, the carbon-hydrogen bonds are formed by the overlap of a $s p^{3}$ hybrid orbital of carbon with a $1 s$ orbital of hydrogen while the carbon-carbon bonds are formed by the overlap of two $s p^{3}$ hybrid orbitals of two carbon atoms (Figure 2.4).

Figure 2.4 Structure of ethane showing overlap of orbitals to form $\mathrm{C}-\mathrm{C}$ and $\mathrm{C}-\mathrm{H}$ bonds
The overlap of the two $s p^{3}$ orbitals to form the carbon-carbon bond takes place along the direction of the orbitals. Such an overlap is called a linear overlap and results in the formation of a $\boldsymbol{\sigma}$ bond.

### 2.1.3 Properties of alkenes and alkynes

Both alkene and alkyne hydrocarbons are unsaturated compounds. Alkenes contain at least one carbon-carbon double bond while alkynes contain at least one carbon-carbon triple bond. Acyclic alkenes with one double bond but without any other functional group form the homologous series of alkenes with the general formula $\mathrm{C}_{\mathrm{n}} \mathrm{H}_{2 \mathrm{n}}$. Alkynes with one triple bond and without any other functional group form the homologous series of alkynes with the general formula $\mathrm{C}_{\mathrm{n}} \mathrm{H}_{2 \mathrm{n}-2}$.

Carbon-carbon double bond of an alkene and carbon-carbon triple bond in alkyne are stronger and shorter than a carbon-carbon single bond (Table 2.3).

Table 2.3 Bond energies and bond lengths of carbon-carbon single, double and triple bonds

| Bond | Bond energy/ $\mathbf{k J ~ m o l}^{-1}$ | Bond length/ pm |
| :--- | :--- | :--- |
| $\mathrm{C}-\mathrm{C}$ | 347 | 154 |
| $\mathrm{C}=\mathrm{C}$ | 611 | 133 |
| $\mathrm{C} \equiv \mathrm{C}$ | 839 | 120 |

Alkenes show boiling points very similar to those of alkanes with the same number of C atoms. Ethene, propene and the isomeric butenes are gases at room temperature. All the rest are liquids. As with alkanes, boiling points of alkenes increase with the increase of molecular mass (chain length). Intermolecular forces of alkenes become stronger with increase in the size of the molecules. As the polarity of alkynes is also low, their physical properties are very similar to those of the corresponding alkanes and alkenes.

### 2.1.4 Structure of alkenes

Ethene $\left(\mathrm{C}_{2} \mathrm{H}_{4}\right)$ is the simplest alkene. It contains a carbon-carbon double bond. Each carbon atom in ethene is $s p^{2}$ hybridized and forms three equivalent $s p^{2}$ hybrid orbitals which lie in the same plane and point to the three corners of an equilateral triangle (Figure 2.5). The unhybridized $p$ orbital lies perpendicular $\left(90^{\circ}\right)$ to this plane.

Figure 2.5 Shape and arrangement of $s p^{2}$ hybrid orbitals an unhybridized $p$ orbital of carbon These $s p^{2}$ orbitals are formed by mixing of the $2 s$ orbital with two $2 p$ orbitals leaving one unhybridized $p$ orbital (Figure 2.6).

Figure 2.6 Graphical representation of $s p^{2}$ hybridization of carbon in ethane
In ethene each carbon uses two $s p^{2}$ orbitals to form two $\mathrm{C}-\mathrm{H}$ bonds each. The remaining $s p^{2}$ orbital in each carbon is used to form a carbon-carbon $\sigma$ bond by linear overlap. The unhybridized $p$ orbitals of each carbon atom which are parallel to each other overlap laterally to form another carbon-carbon bond. This bond formed by the lateral overlap of $p$ orbitals is called a $\pi$ bond. All alkenes contain a carbon-carbon double bond which consists of a $\sigma$ bond and a $\pi$ bond. The $\pi$ bond is weaker than the $\sigma$ bond (Figure 2.7).

Figure 2.7 Structure of ethene showing overlap of orbitals to form $\mathrm{C}-\mathrm{C}$ and $\mathrm{C}-\mathrm{H}$ bonds

The 2 carbon atoms used to form the double bond and the four atoms attached directly to them lie in the same plane. The angle between any two atoms attached to the $s p^{2}$ hybridized carbon will be $120^{\circ}$ (Figure 2.8).

Figure 2.8 Planar shape of ethene $\left(\mathrm{C}_{2} \mathrm{H}_{4}\right)$ molecule

### 2.1.5 Structure of alkynes

Ethyne $\left(\mathrm{C}_{2} \mathrm{H}_{2}\right)$ is the simplest alkyne. It contains a carbon-carbon triple bond. Each carbon atom in ethyne is $s p$ hybridized and forms two equivalent $s p$ hybrid orbitals which lie in the same straight line and point in opposite directions (Figure 2.9). The two unhybridized $p$ orbitals lie perpendicular $\left(90^{\circ}\right)$ to each other and to these two $s p$ orbitals.

Figure 2.9 Shape and arrangement of $s p$ hybrid orbital and unhybridized $p$ orbitals of carbon
These $s p$ orbitals are formed by mixing of the $2 s$ orbital with one $2 p$ orbital leaving two unhybridized $p$ orbitals (Figure 2.10).

Figure 2.10 Graphical representation of $s p$ hybridization of carbon in ethyne
In ethyne each carbon uses one $s p$ orbital to form a $\mathrm{C}-\mathrm{H}$ bond each. The remaining $s p$ orbital in each carbon is used to form a carbon-carbon $\sigma$ bond by linear overlap. The two unhybridized
$p$ orbitals of each carbon atom overlap laterally to form another two carbon-carbon bonds (two $\pi$ bonds). Thus all alkynes contain a carbon-carbon triple bond which consists of a $\sigma$ bond and two $\pi$ bonds (Figure 2.11).

Figure 2.11 Structure of ethyne showing overlap of orbitals to form $\mathrm{C}-\mathrm{C}$ and $\mathrm{C}-\mathrm{H}$ bonds
The 2 carbon atoms used to form the triple bond and the two atoms attached directly to them lie in the same straight line. The angle between the two atoms attached to the $s p$ hybridized carbon will be $180^{\circ}$ (Figure 2.12).

Figure 2.12 Linear shape of ethyne $\left(\mathrm{C}_{2} \mathrm{H}_{2}\right)$ molecule

### 2.2 Chemical reactions of alkanes, alkenes and alkynes in terms of their structures

## Covalent bond cleavage during organic reactions

Any organic reaction involves the cleavage (breaking) and formation of covalent bonds. Bond cleavage can take place in two different ways.
(i) Heterolytic cleavage

In heterolytic cleavage the two electrons involved in the bond will remain with one of the atoms (the more electronegative atom). This will result in a positively charged species (cation) and a negatively charged species (anion).

When writing mechanisms, heterolytic cleavage is shown by a curved arrow which indicates the movement of a pair of electrons.

(ii) Homolytic cleavage

In homolytic cleavage the two electrons involved in the bond will be equally divided such that one electron will remain with each atom. This will result in two neutral species each having one unpaired electron. Such species are called free radicals.

When writing mechanisms, homolytic cleavage is shown by a pair of fishhooks. Each fishhook indicates the movement of a single electron.

### 2.2.1 Reactions of alkanes

In alkanes all the bonds are either $\mathrm{C}-\mathrm{C}$ or $\mathrm{C}-\mathrm{H}$ bonds. Because the polarity of those $\mathrm{C}-\mathrm{C}$ and $\mathrm{C}-\mathrm{H}$ bonds is low, alkanes do not have atoms which bear high positive (electron deficient) or negative charges (electron rich). Therefore, they do not react with common polar reagents such as $\mathrm{OH}^{-}, \mathrm{CN}^{-}, \mathrm{H}^{+}$under normal conditions.

### 2.2.1.1 Chlorination of alkanes

Although alkanes do not react with common polar reagents, they tend to react with free radicals by homolytic cleavage of $\mathrm{C}-\mathrm{H}$ bonds. For example, alkanes react with reagents such as chlorine and bromine free radicals ( Cl atoms and Br atoms) which can be generated by the homolytic cleavage $\mathrm{Cl}_{2}$ and $\mathrm{Br}_{2}$. This can be achieved by irradiation of $\mathrm{Cl}_{2}$ or $\mathrm{Br}_{2}$ with ultra-violet light. Thus, methane in the presence of ultra-violet light reacts with $\mathrm{Cl}_{2}$ to give a mixture of chloromethanes, $\mathrm{CH}_{3} \mathrm{Cl}, \mathrm{CH}_{2} \mathrm{Cl}_{2}, \mathrm{CHCl}_{3}$ and $\mathrm{CCl}_{4}$. These products are formed by a sequence of reactions where the product of one reaction, becomes the starting material for the subsequent reaction of the sequence. Such reactions are called chain reactions.

The mechanism of the reaction is given below. The first step of the reaction is the formation of chlorine free radicals by the homolysis of the covalent bond between two chlorine atoms. This is called the chain initiation step.

The chlorine free radical reacts with $\mathrm{CH}_{4}$ to produce methyl free radical $\left(\cdot \mathrm{CH}_{3}\right)$. The methyl free radical reacts with another molecule of chlorine $\left(\mathrm{Cl}_{2}\right)$ producing $\mathrm{CH}_{3} \mathrm{Cl}$ and Cl . The chlorine radical produced in this step can react either with a molecule of $\mathrm{CH}_{4}$ or a molecule of $\mathrm{CH}_{3} \mathrm{Cl}$ to produce the corresponding carbon free radicals as shown in the reaction sequence given below.

These steps are called chain propagation steps. In these chain propagation steps, free radicals are used and are also generated. Therefore the reaction sequence can proceed without stopping until all the H atoms in $\mathrm{CH}_{4}$ are replaced by Cl . The carbon free radicals produced in this reaction sequence are called reactive intermediates in the free radical chlorination of methane.

A chain reaction can be stopped by chain terminating reactions. There are many chain terminating reactions (steps) that can occur during a chain reaction. In these chain terminating reactions the radicals are used but not generated. A few such chain terminating reactions are shown below.

It should be noted that, as free radical chlorination (and bromination) of alkanes produces a mixture of products, it is of limited use in the synthesis of chloro or bromo hydrocarbons in the laboratory.

### 2.2.2 Reactions of alkenes

The reactions of alkenes take place at the carbon-carbon double bond. Carbon-carbon double bond is formed from a $\sigma$ bond and a $\pi$ bond. The double bond of an alkene is an electron rich area due to the presence of the pi-electron cloud above and below the plane of the alkene. Therefore it can attract a species which can accept a pair of electrons. Such species are electron deficient and are known as electrophiles.

As each of the doubly bonded C atoms is bonded only to three atoms, they are unsaturated and another atom can be attached (added) to each of these two carbon atoms during a reaction.

Therefore the typical reactions of alkenes are electrophilic addition reactions. Let us study the electrophilic addition reaction with its mechanism, using a few examples.

### 2.2.2.1 Addition of hydrogen halides ( $\mathrm{HCl}, \mathrm{HBr}$ or HI )

The electron deficient pole of a hydrogen halide molecule is $\mathrm{H}\left(\mathrm{eg} . \mathrm{H}^{\delta+}-\mathrm{Br}^{\delta-}\right)$. This acts as an electrophile and reacts initially with the double bond. During the reaction the $\mathrm{H}-\mathrm{Br}$ bond breaks releasing a Br - ion. Thus, the H reacts as if it was a $\mathrm{H}^{+}$ion and forms a bond with carbon using the two electrons from the $\pi$-bond.

During these electrophilic addition reactions, intermediate carbocations are formed (Carbocations are electron deficient positively charged trivalent carbon species).

Let us look at the mechanism of addition of HBr to ethene. The reaction proceeds in two steps.

Step 1

Step 2

Carbocations are classified as primary, secondary and tertiary carbocations depending on the number of hydrogen atoms attached to the positively charged carbon atom.

Stability of these carbocations follows the order shown below.

When alkyl groups are attached to the positively charged C atom of the carbocation, stability of the carbocation increases. The reason for this is the release of electrons by the alkyl groups through $\mathrm{C}-\mathrm{C}$ bonds towards the positively charged carbon atom to which they are attached. This results in spreading the positive charge thereby stabilizing the ion. When asymmetrically substituted alkenes undergo electrophilic addition reactions with hydrogen halides, two different carbocations can be formed after the bonding of the electrophile $\left(\mathrm{H}^{+}\right)$. The more stable of these two carbocations forms more easily. Let us take addition of HBr to propene as an example.

The more stable carbocation is obtained when the electrophile gets attached to the carbon atom to which the higher number of hydrogen atoms is attached. This is the explanation for 'Markovnikov's rule' which states that when a protic acid HX adds to an asymmetric alkene, the H adds to the carbon atom bonded to the higher number of H atoms.

The mechanism of addition of HBr to propene can be shown as follows.
Step 1

Step 2

Hydrogen bromide adds in the opposite way to this rule (anti-Markovnikov addition) when there are peroxides in the reaction medium (i.e. the H adds to the carbon bonded to the lower number of H atoms). The reason for this is that in the presence of peroxides the reaction between hydrogen bromide ( HBr ) and the alkenes takes place via a free radical mechanism and not the ionic mechanism described above. A description of the mechanism of this reaction is not expected. It is to be noted that the direction of addition of HCl and HI is not changed in the presence of peroxides.

$$
\mathrm{CH}_{3} \mathrm{CH}=\mathrm{CH}_{2}+\mathrm{HBr} \xrightarrow[\text { (peroxide) }]{\mathrm{RO}-\mathrm{OR}} \mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{Br}
$$

### 2.2.2.2 Addition of bromine to alkenes

Bromine is a not a polar molecule, but polarity is induced in it during the reaction with alkenes. When a bromine molecule approaches the electron rich double bond, a dipole is induced with the Br atom closer to the pi-bond having a partial positive charge. In the first step of the reaction, this Br atom reacts with the double bond and forms a bromonium ion, which is a three membered cyclic intermediate with a positive charge on the Br atom.

In the second step of the reaction, a bromide ion $(\mathrm{Br})$ acting as a nucleophile, forms a bond to one of the carbon atoms bonded to $\mathrm{Br}^{+}$. The bond formed by that carbon atom to $\mathrm{Br}^{+}$is broken during this step, giving an open chain structure again.

The mechanism is as follows.

Step 1

Step 2

### 2.2.2.3 Addition of sulphuric acid and the hydrolysis of the addition product

Alkenes react with cold concentrated sulphuric acid to form alkyl hydrogen sulphates. The reaction is an electrophilic addition reaction and proceeds via a carbocation intermediate as in the case of the addition of HBr .

The reaction is carried out by passing the gaseous alkene through cold concentrated $\mathrm{H}_{2} \mathrm{SO}_{4}$ or stirring the liquid alkene with the cold concentrated $\mathrm{H}_{2} \mathrm{SO}_{4}$. When the solutions of alkyl hydrogen sulphates are diluted with water and heated, they undergo hydrolysis to give an alcohol bearing the same alkyl group as the original alkyl hydrogen sulphate. Let us look at few examples of this reaction.

It is seen that the final product of this sequence of reactions is the alcohol that would be obtained by the Markovnikov addition of water $(\mathrm{H}-\mathrm{OH})$ to the alkene. The same products can be obtained directly by the direct addition of water to alkenes in the presence of dilute sulphuric acid. However the preparation of ethanol by direct addition of water to ethylene is difficult under laboratory conditions.

### 2.2.2.4 Catalytic addition of hydrogen (Hydrogenation)

In the presence of catalysts such as finely powdered $\mathrm{Pt}, \mathrm{Pd}$ or Ni , alkenes react with hydrogen to produce alkanes.

$$
\mathrm{CH}_{3} \mathrm{CH}=\mathrm{CH}_{2} \xrightarrow[\text { Pt or Pd or } \mathrm{Ni}]{\mathrm{H}_{2}} \mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{3}
$$

### 2.2.2.5 Reaction of alkenes with cold, alkaline, dilute potassium permanganate

Alkenes react with cold, alkaline, dilute $\mathrm{KMnO}_{4}$ solution to produce diols (glycols). When this reaction takes place the purple colour of permanganate is disappeared and a brown precipitate of $\mathrm{MnO}_{2}$ is formed. This reaction is used as a test for unsaturation (carbon-carbon double bonds and triple bonds). This is named as Baeyer test for unsaturation. However easily oxidisable substances such as aldehydes will also answer this test.

### 2.2.3 Reactions of alkynes

Alkynes have a triple bond which consists of one sigma bond and two $\pi$ bonds. Alkynes also undergo electrophilic addition reactions with reagents that add to alkenes. The two pi-bonds react independently of each other.

### 2.2.3.1 Addition of bromine

## G.C.E. (A/L) CHEMISTRY: UNIT 8

### 2.2.3.2 Addition of hydrogen halides

### 2.2.3.3 Addition of water

In the presence of $\mathrm{Hg}^{2+}$ and dilute $\mathrm{H}_{2} \mathrm{SO}_{4}$, one molecule of water adds to an alkyne producing an enol. A molecule containing a hydroxyl group attached to a carbon atom in a carbon-carbon double bond is known as an enol.

Enols are unstable and rapidly rearrange to a more stable keto form (aldehydes or ketones)

The addition of water to alkynes takes place according to the Markovnikov's rule as shown below by the reaction of propyne.

### 2.2.3.4 Catalytic addition of hydrogen (Hydrogenation)

Alkynes react with hydrogen in the presence of catalysts such as $\mathrm{Pt}, \mathrm{Pd}$ or Ni to give alkanes.

$$
\mathrm{HC} \equiv \mathrm{CH} \xrightarrow{\mathrm{H}_{2} / \mathrm{Pd}} \mathrm{H}_{3} \mathrm{C}-\mathrm{CH}_{3}
$$

During this reaction the alkyne is first reduced to the alkene which is further reduced to the alkane under the reaction conditions. The reaction can be stopped at the alkene stage by using a less active catalyst. Very often, Pd catalyst deposited on $\mathrm{BaSO}_{4}$ deactivated (poisoned) by quinoline is used.

$$
\mathrm{HC} \equiv \mathrm{CH} \xrightarrow[\text { quinoline }]{\mathrm{H}_{2} / \mathrm{Pd}-\mathrm{BaSO}_{4}} \quad \mathrm{H}_{2} \mathrm{C}=\mathrm{CH}_{2}
$$

### 2.2.4 Acidic nature of alkynes with terminal hydrogen

The triple bond C atoms are $s p$ hybridized. A C-H bond involving a triple bond carbon is formed by the linear overlap of a $s p$ orbital of C and a $s$ orbital of H .

Since a $s p$ orbital has more $s$ character ( $50 \% s$ character) than $s p^{2}$ or $s p^{3}$ orbitals, the bonding electrons in the $\mathrm{C}-\mathrm{H}$ bond of alkynes are closer to the carbon nucleus than in the case of $\mathrm{C}-\mathrm{H}$ bonds in alkenes and alkanes. Therefore the H attached to a triple bond carbon has a higher acidity than the H in alkene or alkane $\mathrm{C}-\mathrm{H}$ bonds. However, the acidity of H attached to terminal alkynes is less than that of water and alcohol.

The H of a terminal alkyne can react as $\mathrm{H}^{+}$with strong bases such as $\mathrm{NaNH}_{2}$ and active metals such as Na . The resulting acetylide anion is stable because the two non-bonded electrons (negatively charged) are close to the carbon nucleus (positively charged).

Terminal alkynes react with certain heavy metal ions such as $\mathrm{Ag}^{+}$and $\mathrm{Cu}^{+}$to form insoluble metal acetylides. These two reactions can be used to identify terminal alkynes.

### 2.3 The nature of bonding in benzene

The molecular formula of benzene is $\mathrm{C}_{6} \mathrm{H}_{6}$ which indicates that it is an unsaturated compound. Under normal conditions benzene does not answer the tests for unsaturation. Therefore, benzene cannot have a structure similar to that of a simple alkene or an alkyne.

### 2.3.1 Structure of benzene

The structure proposed for benzene by Kekulé contained a six-membered ring of carbon atoms with alternating three double and three single bonds (Figure 2.13).

Figure 2.13 Structure of benzene proposed by Kekulé in 1865
This structure was based on the evidence available regarding the relationships of aromatic isomeric compounds. No isomer has been found for any mono-substituted benzene $\left(\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{X} ; \mathrm{X}=-\mathrm{CH}_{3},-\mathrm{C}_{2} \mathrm{H}_{5},-\mathrm{OH},-\mathrm{Cl},-\mathrm{Br},-\mathrm{CHO}\right.$ etc.), implying that all six atoms in benzene are equivalent. Therefore substitution at any one carbon atom will always give a single compound.

It was found that there are three isomeric disubstituted benzenes. Kekulé proposed structures with 1,2-disubstitution, 1,3-disubstitution and 1,4-disubstitution (Figure 2.14), later named as -ortho, -meta and -para isomers.

1,2-bromochlorobenzene (ortho-bromochlorobenzene)

1,3-bromochlorobenzene (meta-bromochlorobenzene)

1,4-bromochlorobenzene (para-bromochlorobenzene)

Figure 2.14 Three isomeric disubstituted benzenes
However these structures implied that two distinct ortho- disubstituted benzenes are possible, depending on whether the substituted carbons are separated by a double bond or a single bond. Since two different ortho- isomers have never been found, Kekulé proposed that benzene molecule could be represented by two equivalent structures which are in equilibrium (Figure 2.15) so that single and double bonds continually interchange positions.

Figure 2.15 Proposed rapid equilibrium of two equivalent structures of ortho-bromochlorobenzene

This proposal explains that benzene has two possible structures and that both of them exist at room temperature. However, no experimental evidence has been found for the existence of two such structures for benzene.

Further the bond length between any two adjacent carbon atoms in benzene is the same. The carbon-carbon bond length of benzene is $1.39 \times 10^{-10} \mathrm{~m}$ which is in-between the length of a carbon-carbon double bond ( $1.34 \times 10^{-10} \mathrm{~m}$ ) and the length of a carbon-carbon single bond ( $1.54 \times 10^{-10} \mathrm{~m}$ ).

The structure of benzene is now considered to be a resonance hybrid of two structures as given in Figure 2.16.

Figure 2.16 Resonance structures of benzene

For convenience, the resonance hybrid of benzene is written as shown below.

Take note of the difference between the resonance sign (the double headed arrow) and the equilibrium sign. In an equilibrium, the compounds shown by structures really exist while in the concept of a resonance hybrid, none of the compounds represented by the structures really exist. They are drawn because there is no other way of representing the real molecule. Each structure contributes to the real structure of the compound. The extent of contribution depends on the relative stability of each resonance structure with the more stable structure making a larger contribution to the real structure. In the case of benzene, both structures have the same stability and contribute equally.

All C atoms of benzene are $s p^{2}$ hybridized. Each carbon bears an unhybridized $p$ orbital which can overlap with the unhybridized $p$ orbitals on either sides of it (Figure 2.17). From this, a cyclic delocalized electron cloud common to all six carbon atoms is formed. Hence, the real structure of benzene is considered to be a hybrid of two Kekulé structures. The real structure of benzene with delocalized electrons is more stable than the hypothetical Kekulé structure with three double bonds. The concept of resonance is used when there are delocalized electrons to be depicted using conventional structures which are drawn using localized bonds.

Figure 2.17 Benzene showing lateral overlap of $p$ orbitals forming a cyclic delocalized electron cloud

### 2.3.2 Stability of benzene

The data for the standard enthalpy of hydrogenation helps to illustrate the stability of a benzene molecule.

Since the standard enthalpy of hydrogenation of cyclohexene (six-membered cyclic hydrocarbon with one double bond) is $-120 \mathrm{~kJ} \mathrm{~mol}^{-1}$, the standard enthalpy of hydrogenation of benzene should be $3 \times-120 \mathrm{~kJ} \mathrm{~mol}^{-1}=-360 \mathrm{~kJ} \mathrm{~mol}^{-1}$ if it possesses three double bonds similar to alkenes. The standard enthalpy of hydrogenation of benzene is found to be $-208 \mathrm{~kJ} \mathrm{~mol}^{-1}$, which is $-152 \mathrm{~kJ} \mathrm{~mol}^{-1}$
less than the expected value for the hydrogenation of three double bonds (Figure 2.18). Hence, benzene is more stable than its Kekulé structure by an amount equal to $(360-208)=152 \mathrm{~kJ} \mathrm{~mol}^{-1}$. This stability is due to the cyclic delocalization of six pi-electrons, and is termed the resonance stabilization (or aromatic stabilization) energy of benzene.

Figure 2.18 Standard enthalpies of hydrogenation of benzene and hypothetical cyclohexatriene.

### 2.4 Characteristic reactions of benzene exemplifying its stability

Benzene contains loosely bound delocalized electron cloud on both faces of the planar benzene molecule. This makes benzene ring electron rich and hence reactive toward electrophiles, similar to alkenes. As we have discussed, benzene shows extra stability due to this delocalization of electrons. Therefore benzene does not easily undergo reactions which destroy this cyclic delocalization. Hence the characteristic reactions of benzene are electrophilic substitution reactions and not electrophilic addition reactions as in the case of alkenes.

### 2.4.1 Electrophilic substitution reactions of benzene

In electrophilic substitution reactions, hydrogen atoms attached to the benzene ring are substituted by electrophiles $\left(\mathrm{E}^{+}\right)$.

The first step in this reaction is the formation of a bond between the electrophile ( $\mathrm{E}^{+}$) and a carbon atom in the benzene ring giving rise to a carbocation (arenium ion). This step is very similar to the first step of the electrophilic addition of HBr to an alkene.

The intermediate carbocation thus formed is stabilized by the delocalization of the positive charge by conjugation with the two $\pi$ bonds. This can be shown by resonance as follows.

However, in going from benzene to the above carbocation the cyclic delocalization of $\pi$ electrons is broken, and the aromatic stabilization energy is lost. It is energetically more favourable for the intermediate carbocation to lose a proton and re-establish the cyclically delocalized electron cloud, than to react with a nucleophile and give an addition product as in the case of alkenes.

The proton is usually taken up by one of the bases ( $\mathrm{B}:^{-}$) present in the reaction mixture. Thus, the result is the substitution of a H atom on the benzene ring with E .

### 2.4.1.1 Nitration

Benzene reacts with a mixture of conc. $\mathrm{HNO}_{3}$ and conc. $\mathrm{H}_{2} \mathrm{SO}_{4}$ to give nitrobenzene which is formed by the substitution of H by a nitro group.

The electrophile in this reaction is ${ }^{+} \mathrm{NO}_{2}$ which is generated in the medium by the dehydration of nitric acid by sulphuric acid as follows.

The ${ }^{+} \mathrm{NO}_{2}$ ion reacts with benzene and in the final step the proton is removed by the hydrogensulphate (bisulphate) ion which act as the base.

### 2.4.1.2 Friedel - Crafts alkylation

Benzene reacts with alkyl halides in the presence of a Lewis acid such as anhydrous $\mathrm{AlCl}_{3}$ to give alkyl benzene, in which a H attached to the benzene is substituted by an alkyl group.

In the case of secondary and tertiary halides (see section 8.6) the electrophile of this reaction is $\mathrm{R}^{+}$, and is generated in the first step by the reaction between alkyl halide and the Lewis acid.

$$
\mathrm{RCl}+\mathrm{AlCl}_{3} \longrightarrow \mathrm{R}^{+}+\mathrm{AlCl}_{4}^{-}
$$

In the final step a proton is removed by $\mathrm{AlCl}_{4}^{-}$.

$$
\mathrm{AlCl}_{4}^{-}+\mathrm{H}^{+} \longrightarrow \mathrm{AlCl}_{3}+\mathrm{HCl}
$$

Let us see an example.

The mechanism of this reaction is as follows.

As you can see the first step of this reaction is formation of carbocation from the alkyl halide. In the second step benzene interacts with this carbocation to form an arenium ion. Removal of proton takes place in the final step restoring the aromatic stability in the product.

In cases where RX is a primary alkyl halide $\left(\mathrm{eg} . \mathrm{CH}_{3} \mathrm{Cl}\right)$ the species actually reacting with the benzene molecule may not be $\mathrm{R}^{+}$, but be a $\mathrm{R}-\mathrm{Cl}$ molecule polarized by coordination to $\mathrm{AlCl}_{3}$, which will transfer $\mathrm{R}^{+}$to the benzene molecule during the reaction by cleavage of the $\mathrm{R}-\mathrm{Cl}$ bond.

The possible mechanism is as follows.

The Friedel - Crafts alkylation does not take place in mono substituted benzenes where the substituent group has a stronger electron attracting ability than halogen. (eg. nitrobenzene).

### 2.4.1.3 Friedel - Crafts acylation

Benzene reacts with acid chlorides in the presence of a Lewis acid such as anhydrous $\mathrm{AlCl}_{3}$, giving acyl benzene, in which a H is substituted by an acyl group.

The electrophile in this reaction is acylium ion $\left(\mathrm{RCO}^{+}\right)$. This is formed in the first step by reacting $\mathrm{AlCl}_{3}$ with acyl chloride as follows.

In the step 2, the acylium ion reacts with benzene to form an arenium ion and in the final step a proton is removed restoring the aromatic stability.

### 2.4.1.4 Halogenation

When benzene reacts with $\mathrm{Cl}_{2}$ or $\mathrm{Br}_{2}$ in the presence of a Lewis acid such as $\mathrm{FeCl}_{3}, \mathrm{FeBr}_{3}, \mathrm{AlCl}_{3}$ or $\mathrm{AlBr}_{3}$, under anhydrous conditions, substitution by a halogen atom takes place in the benzene ring.

The effective electrophile in the above reaction is $\mathrm{Cl}^{+}$. It is transferred to the benzene ring from the complex during the reaction. Proton is removed in the last step restoring the aromatic stability.

### 2.4.2 Resistance of benzene ring towards oxidation

Benzene does not get oxidized by normal oxidizing agents like $\mathrm{H}^{+} / \mathrm{KMnO}_{4}$ due to its stability. However, the alkyl group in alkyl substituted benzene can be oxidized by $\mathrm{H}^{+} / \mathrm{KMnO}_{4}$ to a carboxylic acid group. $\mathrm{H}^{+} / \mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$ can also be used for this oxidation.

Tertiary alkyl groups do not get oxidized under the conditions in which primary and secondary alkyl groups get oxidized. More vigorous conditions under which tertiary alkyl groups can be oxidized also result in cleavage of the benzene ring.

### 2.4.3 Resistance of benzene ring towards hydrogenation

Although benzene does not undergo electrophilic addition reactions, like alkenes, it can undergo addition of hydrogen in the presence of suitable catalysts at higher temperatures in comparison to alkenes.

### 2.5 Directing ability of substituent groups of mono substituted benzene

When a monosubstituted benzene undergoes an electrophilic substitution reaction, the place where the second substituent group attaches will be determined by the nature of the first substituent group. Substituent groups can be categorized into two basic types.

### 2.5.1 Ortho para directing groups

eg. - $\mathrm{OH},-\mathrm{R},-\mathrm{NH}_{2}$, $-\mathrm{NHR},-\mathrm{OCH}_{3}$, halogens
Other than halogen, the ortho para directing groups activate the benzene ring towards electrophilic substitution by making it more electron rich than benzene.

### 2.5.2 Meta directing groups

```
eg. - \(\mathrm{NO}_{2}\), - CHO , -COR, \(-\mathrm{COOH},-\mathrm{COOR}\)
```

Meta directing groups deactivate the benzene ring towards electrophilic substitution by withdrawing electrons from it.

### 2.6 Structure and reactions of alkyl halides

Alkyl halides are classified as primary, secondary or tertiary depending on the number of H atoms attached to the carbon atom which carries the halogen atom.

Secondary alkyl halide

Alkyl halides are polar compounds. Although they are polar, the solubility of alkyl halides in water is very low. One reason for this is that they do not form hydrogen bonds with water.

Due to the higher electronegativity of the halogen atom relative to the carbon atom, the carbonhalogen bond is polarized. As a result, there is a deficiency of electrons in that carbon atom. Therefore, it is possible that nucleophiles attack this position. Nucleophiles are basic, electron rich reagents which can utilize a pair of electrons to form a bond with an electron deficient carbon atom.

A few common examples are:
$\begin{array}{lllllll}\overline{\mathrm{OH}} & \overline{\mathrm{OR}} & \overline{\mathrm{N}} \mathrm{H}_{2} & -\mathrm{CN} & \mathrm{RC} \equiv \overline{\mathrm{C}} & \mathrm{H}_{2} \mathrm{O} & \mathrm{NH}_{3}\end{array}$
Characteristic reactions of alkyl halides are nucleophilic substitution reactions. During nucleophilic substitution reaction, the carbon atom forms a new bond with the nucleophile and the halogen atom leaves as a halide ion.

Let us look at some examples:

As a nucleophile possesses a pair of electrons, any nucleophile can also act as a base by forming a bond with $\mathrm{H}^{+}$. Therefore, when an alkyl halide is reacted with a reagents such as: $\mathrm{OH}^{-}, \mathrm{OR}^{-}$, it can also undergo an elimination reaction by the mechanism shown below.

In this reaction, instead of reacting $\mathrm{OH}^{-}$group as a nucleophile with carbon, it reacts as a base and removes a $\mathrm{H}^{+}$from the carbon atom adjacent to the carbon atom bearing halogen. The hydrogen atoms attached to the carbon atom adjacent to the carbon atom bearing the halogen atoms, have a low acidity due to the polarization of the C-X bond. Thus substitution and elimination are competing reactions in alkyl halides. The balance between substitution and elimination is influenced by the solvent used in the reaction. In the laboratory, aqueous KOH is used when substitution is desired, and ethanolic KOH is used when elimination is desired.

Alkyl halides react with Mg in the medium of dry ether to form Grignard reagents. Grignard reagents are organometallic reagents.

$$
\mathrm{R}-\mathrm{X}+\mathrm{Mg} \xrightarrow{\text { dry ether }} \mathrm{R}-\mathrm{MgX}
$$

When an alkyl halide forms a Grignard reagent the polarity of the carbon atom originally joined to halogen, changes as shown below.

Thus, an electron deficient carbon atom is converted to an electron rich carbon atom. In fact, the alkyl group attached to Mg can utilize the pair of electrons in the $\mathrm{C}-\mathrm{Mg}$ bond and behave as a strong base as well as a strong nucleophile.

Therefore Grignard reagents cannot be prepared or used in organic reactions in the presence of compounds which have even weakly acidic H atoms, including water.

$$
\mathrm{R}-\mathrm{MgX}+\mathrm{H}_{2} \mathrm{O} \longrightarrow \mathrm{RH}+\mathrm{Mg}_{X}^{-\mathrm{OH}}
$$

The strong basic character of the Grignard reagent can be shown by the following reactions.

The last reaction of the above list is the reaction of a Grignard reagent with a terminal alkyne. Note that the product is also another Grignard reagent. This reaction can be used to prepare acetylenic Grignard reagents.

### 2.7 Nucleophilic substitution reactions of alkyl halides in terms of the timing of bond making and bond breaking steps

During reactions, bonds are broken and new bonds are formed. Nucleophilic substitution reactions of alkyl halides involve the breaking of a carbon-halogen bond and the formation of a carbon-nucleophile bond. To study the mechanism of nucleophilic substitution reactions of alkyl halides the time interval between bond breaking and bond making steps can be considered.

When the breaking of the C-X bond and the formation of the new bond to the nucleophile takes place simultaneously, the nucleophilic substitution reaction of the alkyl halide takes place as a one-step reaction.

Accordingly, for the reaction of an alkyl bromide with the hydroxyl ion, the one-step reaction can be presented as follows.

When the breaking of the C-X bond takes place at first and then the formation of the new bond to the nucleophile takes place, the nucleophilic substitution reaction of the alkyl halide takes place as a two-step reaction.

Accordingly, the reaction that takes place by two steps can be presented as follows

Step 1

Step 2

The reaction that takes place by two steps goes through a carbocation intermediate. On considering the stability of the carbocation formed, the tertiary alkyl halides $\left(\mathrm{R}^{1}, \mathrm{R}^{2}, \mathrm{R}^{3}=\right.$ alkyl $)$ which are able to form a more stable tertiary carbocations tend to undergo nucleophilic substitution in two steps. The primary alkyl halides $\left(R^{1}, R^{2}=H, R^{3}=H\right.$ or alkyl) tend to undergo nucleophilic substitution reactions in one step as the primary carbocations they form are less stable.

Generally, both pathways are taken by the secondary alkyl halides $\left(R^{1}=H, R^{2}, R^{3}=\right.$ alkyl $)$ to extents which depend on the reaction conditions.

Vinyl and phenyl carbocations are unstable and therefore, vinyl halides and aryl halides they do not react by the two step pathway. They also do not react by the one step pathway because the $\mathrm{C}-\mathrm{X}$ bond is stronger than in alkyl halides due to its double bond character. This can be shown by resonance.

## G.C.E. (A/L) CHEMISTRY: UNIT 9

## Introduction

The common oxygen containing organic compounds includes alcohols, phenols, ethers, carbonyl compounds (aldehydes and ketones) and carboxylic acids and carboxylic acid derivatives (esters, amides and acid halides). Alcohols are compounds containing OH group attached to aliphatic carbon atom while phenols are aromatic compounds in which an OH group is attached to a benzene ring. Aldehydes, ketones, carboxylic acids and carboxylic acid derivatives all contain a carbonyl $(\mathrm{C}=\mathrm{O})$ group. These classes of compounds differ from each other based on the nature of the two groups attached to the carbonyl carbon.

### 3.1 Structure, properties and reactions of alcohols

Alcohols are compounds containing an $\mathrm{O}-\mathrm{H}$ group attached to a $s p^{3}$ hybridized carbon atom. Alcohols with one OH group are called monohydric alcohols while those with two, three, four etc. are called dihydric alcohols, trihydric alcohols, tetrahydric alcohols etc. Compounds with many OH groups are commonly called polyhydric alcohols. Our discussion will be mainly confined to monohydric alcohols.

### 3.1.1 Classification of monohydric alcohols

Similar to the alkyl halides monohydric alcohols are classified into three types depending on the number of H atoms attached to the carbon atom bearing the OH group (carbinol carbon atom) as primary ( 2 H atoms), secondary ( 1 H atom) and tertiary (no H atoms attached) as shown below.

### 3.1.2 Physical properties

In alcohols the $\mathrm{O}-\mathrm{H}$ bond is polarized as $\mathrm{R}-\mathrm{O}^{\delta}--\mathrm{H}^{\delta+}$. Hence, inter-molecular hydrogen bonds are formed between alcohol molecules (Figure 3.1).

Figure 3.1 Intermolecular H -bonding in ethanol
Because of these relatively strong intermolecular bonds, the boiling points of alcohols have higher values compared to the alkanes and ethers with comparable relative molecular masses (Table 3.1). The boiling point increases in going down the series of alcohols. Similar to alkanes, branching of the alkyl part of the molecule leads to a reduction of boiling point.

Table 3.1 Boiling points of alcohols, ethers and alkanes of comparable relative molecular masses

| Compound | Structural formula | Relative molecular <br> mass | Boiling point $/{ }^{\circ} \mathrm{C}$ |
| :--- | :--- | :--- | :---: |
| ethanol | $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}$ | 46 | 78 |
| dimethyl ether | $\mathrm{CH}_{3} \mathrm{OCH}_{3}$ | 46 | -25 |
| propane | $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{3}$ | 44 | -42 |
| 1-propanol | $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{OH}$ | 60 | 97 |
| 2-propanol | $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CHOH}$ | 60 | 83 |
| ethylmethyl ether | $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OCH}_{3}$ | 60 | 11 |
| butane | $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3}$ | 58 | 0 |
| 1-butanol | $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{OH}$ | 74 | 118 |
| 2-butanol | $\mathrm{CH}_{3} \mathrm{CH}_{(\mathrm{OH}) \mathrm{CH}_{2} \mathrm{CH}_{3}}$ | 74 | 99 |
| 2-methyl-2-propanol | $\left(\mathrm{CH}_{3}\right)_{3} \mathrm{COH}_{3}$ | 74 | 82 |
| diethyl ether | $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OCH}_{2} \mathrm{CH}_{3}$ | 74 | 35 |
| pentane | $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3}$ | 72 | 36 |
| 1-pentanol | $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{OH}$ | 88 | 138 |
| ethyl propyl ether | $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{OCH}_{2} \mathrm{CH}_{3}$ | 88 | 64 |
| hexane | $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}$ | 86 | 68 |

Alcohols with low relative molecular masses are soluble in water. The solubility of alcohols in water is due to the OH group which can forms H - bonds with water molecules. The non-polar alkyl group in the alcohol molecule is a hindrance to the solubility in water. In going down the homologous series of alcohols the size of the non - polar alkyl group gradually increases relative to the OH group. Accordingly the solubility of alcohols in water gradually decreases (Table 3.2).
Table 3.2 Boiling points and solubility (in water) of some long chain alcohols

| Alcohol | Structural formula | Boiling point/ ${ }^{\circ} \mathrm{C}$ | Solubility $\left(\mathbf{g} / \mathbf{1 0 0 g} \mathrm{H}_{2} \mathrm{O}\right)$ |
| :--- | :--- | :--- | :--- |
| methanol | $\mathrm{CH}_{3} \mathrm{OH}$ | 65 | $\infty$ |
| ethanol | $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}$ | 78 | $\infty$ |
| 1-propanol | $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{OH}$ | 82 | $\infty$ |
| 1-butanol | $\mathrm{CH}_{3}\left(\mathrm{CH}_{2}\right)_{2} \mathrm{CH}_{2} \mathrm{OH}$ | 118 | 7.9 |
| 1-penatanol | $\mathrm{CH}_{3}\left(\mathrm{CH}_{2}\right)_{3} \mathrm{CH}_{2} \mathrm{OH}$ | 138 | 2.3 |
| 1-hexanol | $\mathrm{CH}_{3}\left(\mathrm{CH}_{2}\right)_{4} \mathrm{CH}_{2} \mathrm{OH}$ | 158 | 0.6 |

| 1-octanol | $\mathrm{CH}_{3}\left(\mathrm{CH}_{2}\right)_{6} \mathrm{CH}_{2} \mathrm{OH}$ | 195 | 0.05 |
| $\infty$ - Miscible in any proportion. |  |  |  |

## G.C.E. (A/L) CHEMISTRY: UNIT 9

### 3.1.3 Reactions of alcohols

Alcohols undergo reactions involving cleavage of $\mathrm{O}-\mathrm{H}$ bond and cleavage of $\mathrm{C}-\mathrm{O}$ bond.

### 3.1.3.1 Reactions involving cleavage of $\mathrm{O}-\mathrm{H}$ bond

(a) Reaction with sodium (and other alkali metals)

Alcohols show acidic behaviour because of the polarization of the $\mathrm{O}-\mathrm{H}$ bond and react with sodium liberating hydrogen and forming sodium alkoxides. The alkoxide ion is a strong nucleophile and also a strong base.

$$
\mathrm{RO}-\mathrm{H}+\mathrm{Na} \longrightarrow \mathrm{RO}^{-}+\mathrm{H}_{2}
$$

However alcohols are not acidic enough to give a substantial reaction with sodium hydroxide to give sodium alkoxide. Thus the equilibrium shown below lies essentially on the side of the alcohol. Hence alcohols are weaker acids than water.

$$
\mathrm{ROH}+\mathrm{NaOH} \rightleftharpoons \mathrm{RO}^{-} \mathrm{Na}^{+}+\mathrm{H}_{2} \mathrm{O}
$$

(b) Reaction with carboxylic acid (Acylation of alcohols to give esters)

Alcohols react with carboxylic acids to form esters (esterification reaction). Concentrated $\mathrm{H}_{2} \mathrm{SO}_{4}$ acid acts as a catalyst for this esterification reaction.

$$
\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}+\mathrm{CH}_{3} \mathrm{COOH} \xlongequal{\text { conc. } \mathrm{H}_{2} \mathrm{SO}_{4} / \text { heat }} \mathrm{CH}_{3} \mathrm{COOC}_{2} \mathrm{H}_{5}+\mathrm{H}_{2} \mathrm{O}
$$

### 3.1.3.2 Nucleophilic substitution reactions involving cleavage of C-O bond

(a) Reaction with hydrogen halides ( HBr or HI )

Alcohols undergo nucleophilic substitution reaction with HBr or HI to give the corresponding alkyl bromides or alkyl iodides. Protonation of the O atom in the presence of acid ( HBr or HI ), converts the -OH group into a better leaving group $\left(\mathrm{H}_{2} \mathrm{O}\right)$.

This is a nucleophilic substitution reaction. In this reaction $\mathrm{Br}^{-}$ion acts as the nucleophile and the leaving group is $\mathrm{H}_{2} \mathrm{O}$.

Alcohols react with HCl only in the presence of Lewis acids or acids.
The Lucas test to distinguish primary, secondary and tertiary alcohols makes use of this fact. In this reaction, ROH is converted to $\mathrm{RCl} . \mathrm{ZnCl}_{2}$ which is a Lewis acid acts as the catalyst in this reaction. Because alkyl halides are insoluble in water, as the reaction proceeds the reaction mixture becomes cloudy and turbid. The time taken for the turbidity to appear, after the mixing of reagents, can be used to distinguish between primary, secondary and tertiary alcohols. Under the given reaction conditions the above nucleophilic substitution reaction takes place in two steps. Tertiary alcohols form stable
intermediate tertiary carbocations and therefore, tertiary alcohols in the presence of the Lucas reagent form turbidity in a very short time. Secondary alcohols take longer time to produce turbidity and primary alcohols react very slowly.
(b) Reaction with phosphorus trihalides $\left(\mathrm{PCl}_{3}\right.$ or $\left.\mathrm{PBr}_{3}\right)$

Alcohols react with $\mathrm{PCl}_{3}$ and $\mathrm{PBr}_{3}$ to give alkyl chlorides and alkyl bromides respectively.

$$
\begin{aligned}
& 3 \mathrm{ROH}+\mathrm{PCl}_{3} \longrightarrow 3 \mathrm{RCl}+\mathrm{H}_{3} \mathrm{PO}_{3} \\
& 3 \mathrm{ROH}+\mathrm{PBr}_{3} \longrightarrow 3 \mathrm{RBr}+\mathrm{H}_{3} \mathrm{PO}_{3}
\end{aligned}
$$

(c) Reaction with phosphorus pentachloride $\left(\mathrm{PCl}_{5}\right)$

Alcohols react with $\mathrm{PCl}_{5}$ to give alkyl chlorides.

$$
\mathrm{ROH}+\mathrm{PCl}_{5} \longrightarrow \mathrm{RCl}+\mathrm{POCl}_{3}+\mathrm{HCl}
$$

Reactions of alcohols with phosphorous halides described in (b) and (c) above are also nucleophilic substitution reactions where the halide ion acts as the nucleophile.

### 3.1.3.3 Elimination reaction

Alcohols undergo an elimination reaction when heated with conc. $\mathrm{H}_{2} \mathrm{SO}_{4}$ or when heated with alumina to a higher temperature. The reaction is the dehydration of alcohols, in which a molecule of water is eliminated from an alcohol. During this reaction an alkene is formed as the product.

### 3.1.3.4 Oxidation of alcohols

Alcohols can be oxidized with several oxidizing agents. The product of oxidation depends on whether the alcohol is primary, secondary or tertiary. Oxidation of alcohols can be carried out with $\mathrm{H}^{+} / \mathrm{KMnO}_{4}$ or $\mathrm{H}^{+} / \mathrm{K}_{2} \mathrm{Cr}_{2} \mathrm{O}_{7}$ or $\mathrm{H}^{+} / \mathrm{CrO}_{3}$.

## (a) Oxidation of primary alcohols

Primary alcohols are oxidized to carboxylic acids through the corresponding aldehyde with the above oxidizing reagents.

The oxidation reaction will be stopped at the stage where aldehyde is formed when pyridinium chlorochromate $\left[\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{NH}\right]^{+}\left[\mathrm{CrO}_{3} \mathrm{Cl} \Gamma\right.$ (PCC) is used.

(b) Oxidation of secondary alcohols

Secondary alcohols are oxidized to give ketones with any of the above reagents.

(c) Oxidation of tertiary alcohols

Generally the tertiary alcohols do not undergo oxidation under conditions that primary and secondary alcohols are oxidized.

### 3.2 Structure, properties and reactions of phenols

### 3.2.1 Acidity of phenols

Aromatic compounds, in which an OH group is joined directly to a carbon atom of a benzene ring, are called phenols. Alcohols and phenols dissociate in aqueous solutions as shown below.

$$
\begin{aligned}
& \mathrm{ROH}+\mathrm{H}_{2} \mathrm{O} \rightleftharpoons \mathrm{RO}^{-}+\mathrm{H}_{3} \mathrm{O}^{+} \\
& \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{OH}+\mathrm{H}_{2} \mathrm{O} \rightleftharpoons \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}^{-}+\mathrm{H}_{3} \mathrm{O}^{+}
\end{aligned}
$$

Phenols are more acidic than alcohols. This means that in the above equilibria, the equilibrium point for phenols is more towards the right than alcohols. The reason for this is that the stability of phenoxide ion relative to phenol is greater than the stability of the alkoxide ion relative to the alcohol. This can be understood by considering the resonance structures for phenol and its anion.

Figure 3.2 Resonance structures of phenol and phenoxide ion
The stabilization of the anion by resonance is greater than the stabilization of the phenol because unlike in the phenol there is no charge separation in the resonance structures of the anion (Figure 3.2). There is no corresponding resonance stabilization of alcohol or its anion.

## G.C.E. (A/L) CHEMISTRY: UNIT 9

### 3.2.2 Reactions involving cleavage of the $\mathrm{O}-\mathrm{H}$ bond

The higher acidity of phenols is confirmed by the following examples. Unlike alcohols, phenols react with NaOH to give sodium phenoxide. However, neither phenols nor alcohols are acidic enough to react with $\mathrm{NaHCO}_{3}$ and evolve $\mathrm{CO}_{2}$.

$$
\begin{aligned}
& 2 \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{OH}+2 \mathrm{Na} \longrightarrow 2 \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}^{-} \mathrm{Na}^{+}+\mathrm{H}_{2} \\
& \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{OH}+\mathrm{NaOH} \longrightarrow \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}^{-} \mathrm{Na}^{+}+\mathrm{H}_{2} \mathrm{O}
\end{aligned}
$$

### 3.2.3 Non-occurrence of nucleophilic substitution reactions by breaking C-O bond

Unlike alcohols phenols do not undergo nucleophilic substitution reactions. Neither the one step nor the two step mechanism takes place because,
(a) The $\mathrm{C}-\mathrm{O}$ bond is shorter ( $s p^{2}$ hybridized C atom) and stronger (double bond nature) due to delocalization of lone pair of electrons on the oxygen atom into the benzene ring. This can be shown by resonance.

(b) Phenyl cation is unstable.

### 3.3 Reactivity of the benzene ring in phenols

The benzene ring in phenol is electron rich compared to benzene due to the delocalization of a lone pair of electrons on the oxygen atom over the benzene ring in phenol. Therefore the benzene ring in phenol is more reactive towards electrophilic reagents than benzene itself. The $\mathrm{O}-\mathrm{H}$ group of phenol directs the electrophilic substitution to the ortho and para positions with respect to the phenolic OH group.

When the electrophilic substitution reactions of phenol are compared with the corresponding reactions of benzene along with the relevant conditions, it is clear that the benzene ring of phenol is more reactive towards electrophiles. Consider the following examples.

### 3.3.1 Reaction of phenol with $\mathrm{Br}_{2}$

Phenol reacts readily with bromine to form 2,4,6-tribromophenol while benzene does not react with bromine.

When this reaction is carried out with bromine water 2,4,6-tribromophenol is observed as a white precipitate.

### 3.3.2 Nitration of phenol

Nitration occurs even with dilute $\mathrm{HNO}_{3}$ at $20^{\circ} \mathrm{C}$ while benzene requires conc. $\mathrm{HNO}_{3} /$ conc. $\mathrm{H}_{2} \mathrm{SO}_{4}$ and higher temperatures for nitration.

It should be noted that Friedel-Crafts alkylation reactions cannot be carried out with phenols because of the complex formation between Friedel-Crafts catalyst and phenols.

### 3.4 Structure, properties and reactions of aldehydes and ketones

Both aldehydes and ketones contain the carbonyl $(\mathrm{C}=\mathrm{O})$ functional group. In aldehydes the carbonyl carbon is attached to an H atom and an alkyl or aryl (aromatic) group. However, the simplest aldehyde, formaldehyde (methanal) has two H atoms attached to the carbonyl carbon. In ketones each of the groups attached to the carbonyl carbon is either an alkyl group or an aryl group. The carbonyl C atom is $s p^{2}$ hybridized and the three atoms attached to it lie in one plane (trigonal planar). The carbon oxygen double bond consists of a $\sigma$ bond and a $\pi$ bond.

### 3.4.1 Physical properties

Boiling points of aldehydes and ketones are higher than those of alkanes of comparable relative molecular masses due to the presence of intermolecular dipole-dipole interactions. However their boiling points are lower than alcohols of comparable relative molecular masses as they do not form intermolecular H-bonds (Table 3.3).

Table 3.3 Boiling points and water solubility of aldehydes, ketones, alcohols and alkanes of comparable relative molecular masses

| Compound | Structural formula | Relative molecular mass | Boiling point/ ${ }^{\circ} \mathrm{C}$ | Water Solubility (g/100 mL)* |
| :---: | :---: | :---: | :---: | :---: |
| ethanal | $\mathrm{CH}_{3} \mathrm{CHO}$ | 44 | 21 | $\infty$ |
| ethanol | $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}$ | 46 | 78 | $\infty$ |
| propane | $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{3}$ | 44 | -42 | none |
| propanal | $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CHO}$ | 58 | 49 | 16 |
| propanone | $\mathrm{CH}_{3} \mathrm{COCH}_{3}$ | 58 | 56 | $\infty$ |
| 1-propanol | $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{OH}$ | 60 | 97 | $\infty$ |
| 2-propanol | $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CHOH}$ | 60 | 83 | $\infty$ |
| butane | $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3}$ | 58 | 0 | none |
| butanal | $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CHO}$ | 72 | 76 | 7 |
| 2-butanone | $\mathrm{CH}_{3} \mathrm{COCH}_{2} \mathrm{CH}_{3}$ | 72 | 80 | 26 |
| 1-butanol | $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{OH}$ | 74 | 118 | 7.9 |
| 2-butanol | $\mathrm{CH}_{3} \mathrm{CH}(\mathrm{OH}) \mathrm{CH}_{2} \mathrm{CH}_{3}$ | 74 | 99 | 29 |
| pentane | $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3}$ | 72 | 36 | none |
| penatanal | $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CHO}$ | 86 | 103 | 1 |
| 2-pentanone | $\mathrm{CH}_{3} \mathrm{COCH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3}$ | 86 | 102 | 6 |
| 1-pentanol | $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{OH}$ | 88 | 138 | 2.3 |
| hexane | $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CH}_{3}$ | 86 | 68 | none |

$\infty$ - Miscible in any proportion.
However aldehydes and ketones can participate in intermolecular H-bonding with water (Figure 3.3). Therefore aldehydes and ketones with relatively lower molecular masses are soluble in water (Table 3.3).

Figure 3.3 Intermolecular H-bonding of aldehydes and ketones with water

### 3.4.2 Reactions of aldehydes and ketones

The carbonyl group is a polar group because of the electron negative O atom $\left({ }^{\delta+} \mathrm{C}=\mathrm{O}^{\delta-}\right)$. Hence the C atom is electron deficient and can react with a nucleophile. The C atom is unsaturated because it is attached only to three atoms. It can therefore form a new bond with a nucleophile. During this process the two $\pi$ electrons are transferred to the oxygen atom which thereby acquiring a negative charge. This negative charge is neutralized by the attachment of a positively charged species (very often a proton). Therefore the characteristic reactions of aldehydes and ketones are nucleophilic addition reactions.

## G.C.E. (A/L) CHEMISTRY: UNIT 9

### 3.4.3 Nucleophilic addition reactions

### 3.4.3.1 Addition of HCN to aldehydes and ketones

Addition of HCN to aldehydes and ketones is a nucleophilic addition reaction. This is carried out by adding a dilute mineral acid into a mixture of the carbonyl compound and an aqueous solution of sodium cyanide. Here the $\mathrm{CN}^{-}$ion acts as the nucleophile.

Mechanism of the reaction is as follows.

### 3.4.3.2 Reaction with Grignard reagents

In Grignard reagents the $\mathrm{C}-\mathrm{Mg}$ bond is polarized as follows.

Therefore the R group of the Grignard reagent together with the electron pair of $\mathrm{R}-\mathrm{Mg}$ bond reacts as a nucleophile with the carbonyl carbon. This leads to the formation of an alkoxy magnesium halide.

Hydrolysis of the alkoxy magnesium halide gives the corresponding alcohol. This is carried out by an aqueous acid.

The overall reaction is as follows:

All aldehydes except formaldehyde give secondary alcohols whereas ketones give tertiary alcohols with Grignard reagents. Formaldehyde gives primary alcohols.

Grignard reagents are prepared and reacted with aldehydes and ketones under anhydrous conditions. Hence the formation of the alkoxy magnesium halide and its hydrolysis are two distinct steps.

## G.C.E. (A/L) CHEMISTRY: UNIT 9

### 3.4.3.3 Reaction with 2,4-dinitrophenylhydrazine (2,4-DNP or Brady reagent)

In this reaction, nucleophilic addition of 2,4-dinitrophenylhydrazine to the aldehyde or ketone takes place first. Then a water molecule is eliminated from the intermediate product to form the final product, which is a 2,4-dinitrophenylhydrazone.

Although this reaction takes place in two steps as shown above, the hydroxy product first obtained by the nucleophilic addition cannot be isolated under the reaction conditions and dehydrates to give the final product. This reaction is used to identify aldehydes and ketones.

### 3.4.4 Self-condensation reactions of aldehydes and ketones

Due to the strong electron withdrawing nature of the carbonyl group, H atoms attached to the carbon atoms directly bound to the carbonyl carbon (the $\alpha-\mathrm{H}$ ) become acidic. This $\alpha-\mathrm{H}$ can be abstracted as a proton by a base (e.g.: OH ). The carbanion so formed is stabilized by resonance as shown below.

This carbanion reacts as a nucleophile and attacks the carbon atom of the carbonyl group of an un-ionized aldehyde molecule. Hence aldehydes and ketones with $\alpha$-hydrogens undergo base catalyzed self-condensation reactions.

## G.C.E. (A/L) CHEMISTRY: UNIT 9 Oxygen Containing Organic Compounds

Let us see some examples.
Reaction of acetaldehyde in the presence of aqueous NaOH

The overall reaction is:

Condensation of acetone in the presence of aqueous NaOH

The overall reaction is:

The addition products obtained above undergo dehydration easily when heated with acids.

### 3.4.5 Reduction of aldehydes and ketones by lithium aluminium hydride $\left(\mathrm{LiAlH}_{4}\right)$ or sodium borohydride $\left(\mathrm{NaBH}_{4}\right)$

Aldehydes are reduced to primary alcohols with $\mathrm{LiAlH}_{4}$ or $\mathrm{NaBH}_{4}$ while ketones are reduced to give secondary alcohols. In these reductions both $\mathrm{LiAlH}_{4}$ and $\mathrm{NaBH}_{4}$ provide hydride ions $\left(\mathrm{H}^{-}\right)$. The hydride ion reacts with the carbonyl C as a nucleophile. Thus these reductions can be considered as nucleophilic addition reactions.

Note that $\mathrm{LiAlH}_{4}$ is too reactive to be used in the presence of water or methanol.

### 3.4.6 Reduction of aldehydes and ketones by $\mathrm{Zn}(\mathrm{Hg})$ / conc. HCl (Clemmenson reduction)

In this reduction reaction, $\mathrm{C}=\mathrm{O}$ group is reduced to a methylene $\left(\mathrm{CH}_{2}\right)$ group. Thus, both aldehydes and ketones can be converted to hydrocarbons.

### 3.4.7 Oxidation of aldehydes

Aldehydes are oxidized to carboxylic acids by oxidizing agents such as acidified potassium dichromate, acidified chromic oxide or acidified potassium permanganate and even by mild oxidizing agents such as Tollen reagent and Fehling solution. In acidic medium aldehydes are oxidized to carboxylic acids while with Tollen and Fehling solution, which are alkaline, the product is a salt of the carboxylic acid. Ketones do not undergo oxidation with these reagents.

### 3.4.7.1 Oxidation by Tollens reagent

Tollens reagent, is a solution containing $\mathrm{Ag}^{+}$in the form $\left[\mathrm{Ag}\left(\mathrm{NH}_{3}\right)_{2}\right]^{+}$. During the oxidation of aldehydes to carboxylic acids, $\mathrm{Ag}^{+}$ions are reduced to metallic silver giving a silver mirror in the test tube.

## G.C.E. (A/L) CHEMISTRY: UNIT 9 <br> Oxygen Containing Organic Compounds

Oxidation of aldehydes by Tollens reagent or the silver mirror test is used to distinguish between aldehydes and ketones.

### 3.4.7.2 Oxidation by Fehling solution

A solution of Copper (II) tartrate in aqueous NaOH is known as Fehling solution. This is a dark blue solution. When a few drops of an aldehyde are added to this reagent and heated, the blue colour of the solution gradually disappears and a brick red precipitate of cuprous oxide is formed.

Aldehydes and ketones can be distinguished from each other by reacting with Fehling solution.

### 3.4.7.3 Oxidation by acidified potassium dichromate or acidified chromic oxide or acidified potassium permanganate

Aldehydes get oxidized to carboxylic acids by reacting with oxidizing agents such as acidified potassium dichromate or acidified chromic oxide or acidified potassium permanganate.

The pink colour of $\mathrm{H}^{+} / \mathrm{KMnO}_{4}$ solution becomes colourless in the presence of an aldehyde while the orange colour of $\mathrm{H}^{+} / \mathrm{Cr}_{2} \mathrm{O}_{7}^{2-}$ solution turns green. By using these reagents aldehydes and ketones can be distinguished from each other.

Since ketones do not contain an H atom attached to the $\mathrm{C}=\mathrm{O}$ group, they do not undergo oxidation with these oxidizing reagents.

However strong oxidizing agents like potassium permanganate can oxidize ketones when heated. During this oxidation carbon-carbon bonds are broken resulting in the decomposition of the ketone.

### 3.5 Structure, properties and reactions of carboxylic acids

Carboxylic acids are compounds containing carboxyl ( COOH ) group which consists of a $\mathrm{C}=\mathrm{O}$ and OH groups (Figure 3.4). Carboxylic acids are generally more acidic than other organic compounds containing OH groups but weaker than the common mineral acids.

Figure 3.4 Structure of the carboxyl group

### 3.5.1 Physical properties

Carboxyl group is a polar functional group. Due to the polarity of $\mathrm{C}-\mathrm{O}$ and $\mathrm{O}-\mathrm{H}$ groups it forms intermolecular hydrogen bonds. Carboxylic acids are capable of forming dimeric structures in which carboxylic acid molecules are attached by hydrogen bonds as pairs (Figure 3.5).

Figure 3.5 Dimeric structure of carboxylic acids due to H-bonding
Due to these reasons carboxylic acids show higher boiling points than the alcohols, aldehydes and ketones with comparable relative molecular masses (Table 3.4).

Table 3.4 Boiling points of some carboxylic acids, alcohols, aldehydes and ketones of comparable relative molecular masses

| Compound | Structural formula | Relative molecular <br> mass | Boiling point/ ${ }^{\circ} \mathrm{C}$ |
| :--- | :--- | :--- | :---: |
| methanoic acid | $\mathrm{HCO}_{2} \mathrm{H}$ | 46 | 100 |
| ethanol | $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}$ | 46 | 78 |
| ethanal | $\mathrm{CH}_{3} \mathrm{CHO}$ | 44 | 20 |
| ethanoic acid | $\mathrm{CH}_{3} \mathrm{CO}_{2} \mathrm{H}$ | 60 | 118 |
| 1-propanol | $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{OH}$ | 60 | 97 |
| 2-propanol | $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CHOH}$ | 60 | 83 |
| propanal | $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CHO}$ | 58 | 49 |
| propanone | $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{C}=\mathrm{O}$ | 58 | 56 |
| propanoic acid | $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CO} \mathrm{H}_{2}$ | 74 | 141 |
| 1-butanol | $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH} \mathrm{CH}_{2} \mathrm{OH}$ | 74 | 118 |
| 2-butanol | $\mathrm{CH}_{3}{\mathrm{CH}(\mathrm{OH}) \mathrm{CH}_{2} \mathrm{CH}}_{3}$ | 74 | 99 |
| butanal | $\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{CH}_{2} \mathrm{CHO}^{2}$ | 72 | 75 |
| butanone | $\mathrm{CH}_{3} \mathrm{COCH}_{2} \mathrm{CH}_{3}$ | 72 | 80 |

Carboxyl group can form H -bonds with water. Therefore carboxylic acids of $\mathrm{C}_{1}$ to $\mathrm{C}_{4}$ dissolve well in water. When the number of carbon atoms increases solubility decreases. Aromatic
carboxylic acids are water insoluble and exist as solid crystalline substances. Almost all the carboxylic acids are soluble in organic solvents.

### 3.5.2 Comparison of the reactivity pattern of -COOH group with $>\mathrm{C}=\mathbf{O}$ group in aldehydes and ketones and - OH group in alcohols and phenols

Similar to alcohols, the $\mathrm{O}-\mathrm{H}$ group of carboxylic acids also undergoes reactions involving cleavage of both $\mathrm{C}-\mathrm{O}$ bond and $\mathrm{O}-\mathrm{H}$ bond.

### 3.5.2.1 Reactions involving cleavage of the $\mathbf{O}-\mathrm{H}$ bond

Carboxylic acids are acidic. They react with alkali metals such as sodium and potassium, alkali such as NaOH and KOH and bases such as $\mathrm{Na}_{2} \mathrm{CO}_{3}$ and $\mathrm{NaHCO}_{3}$.
$2 \mathrm{RCOOH}+2 \mathrm{Na} \longrightarrow 2 \mathrm{RCOO}^{-} \mathrm{Na}^{+}+\mathrm{H}_{2}$
$\mathrm{RCOOH}+\mathrm{NaOH} \longrightarrow \mathrm{RCOO}^{-} \mathrm{Na}^{+}+\mathrm{H}_{2} \mathrm{O}$
$2 \mathrm{RCOOH}+\mathrm{Na}_{2} \mathrm{CO}_{3} \longrightarrow 2 \mathrm{RCOO}^{-} \mathrm{Na}^{+}+\mathrm{CO}_{2}+\mathrm{H}_{2} \mathrm{O}$
$\mathrm{RCOOH}+\mathrm{NaHCO}_{3} \longrightarrow \mathrm{RCOO}^{-} \mathrm{Na}^{+}+\mathrm{CO}_{2}+\mathrm{H}_{2} \mathrm{O}$

A comparison of the reactions of alcohols, phenols and carboxylic acids with sodium, sodium hydroxide and sodium bicarbonate is given in the Table 3.5.

Table 3.5 Reactions of alcohols, phenols and carboxylic acids with sodium, sodium hydroxide, sodium carbonate and sodium bicarbonate

| Compound | Reaction with |  |  |
| :---: | :---: | :---: | :---: |
|  | Metallic Na | aq. NaOH | aq. $\mathrm{Na}_{2} \mathrm{CO}_{3}$ or $\mathrm{NaHCO}_{3}$ |
| $\mathrm{R}_{\mathrm{H}}$ | Liberates $\mathrm{H}_{2}$ gas forming $\mathrm{RO}^{-} \mathrm{Na}^{+}$ | No reaction | No reaction |
|  | Liberates $\mathrm{H}_{2}$ gas forming $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{ONa}^{+}$ | Dissolves in aq. NaOH forming a solution of $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}^{-} \mathrm{Na}^{+}$ | No reaction |
| $\mathrm{R}-\frac{C_{0}^{\prime \prime}}{\mathrm{O}-\mathrm{H}}$ | Liberates $\mathrm{H}_{2}$ gas forming $\mathrm{RCOONa}^{+}$ | Dissolves in aq. NaOH forming a solution of RCOO Na ${ }^{+}$ | Dissolves in aq. <br> $\mathrm{Na}_{2} \mathrm{CO}_{3}$ or aq. <br> $\mathrm{NaHCO}_{3}$ forming <br> a solution of <br> $\mathrm{RCOONa}^{+}$and <br> liberating $\mathrm{CO}_{2}$ gas |

Thus the acidic strengths of alcohols, phenols and carboxylic acids vary as follows.

$$
\text { Alcohols }<\text { Phenols }<\text { Carboxylic acids }
$$

In aqueous medium carboxylic acids exist in the following equilibrium.

The equilibrium point of the above equilibrium is more shifted towards the right side relative to the corresponding equilibrium attained by the phenols. The reason for this is that the stabilization of the carboxylate ion relative to the carboxylic acid is greater than the stabilization of the phenoxide ion relative to phenol. Both the carboxylate ion and carboxylic acid are stabilized by resonance (Figure 3.6) as in the case of phenoxide ion and phenols (Figure 3.2).

Resonance structures of a carboxylic acid

Resonance structures of a carboxylate anion

Figure 3.6 Resonance structures of a carboxylic acid and a carboxylate anion
The stabilization of the carboxylate anion by resonance is greater than the stabilization of the acid because unlike in the acid there is no charge separation in the resonance structures of the anion (Figure 3.6).

The higher acidity of the carboxylic acids can be explained by the fact that the carboxylate ion is stabilized by the delocalization of the negative charge between two equivalent electronegative oxygen atoms in contrast to the delocalization of the negative charge on oxygen and carbon atoms in phenoxide anion.

### 3.5.2.2 Reactions involving cleavage of the $\mathbf{C}-\mathrm{O}$ bond

(a) Reaction with $\mathrm{PCl}_{3}$ or $\mathrm{PCl}_{5}$

Carboxylic acids react with $\mathrm{PCl}_{3}$ or $\mathrm{PCl}_{5}$ giving carboxylic acid chlorides.

(b) Reaction with alcohols

Carboxylic acids react with alcohols in the presence of acid catalyst to give esters.

Although the above reaction appears to be a simple nucleophilic substitution reaction $\left(\mathrm{OH}\right.$ being replaced by $\left.\mathrm{OC}_{2} \mathrm{H}_{5}\right)$ it actually involves first the nucleophilic addition of the $\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}$ molecule across the $\mathrm{C}=\mathrm{O}$ to give a tetrahedral intermediate. Under acidic condition of the reaction this intermediate loses a molecule of water to give the ester.

Note: Please also see the discussion in the Section 3.6.

### 3.5.2.3 Reduction of carboxylic acids with $\mathrm{LiAlH}_{4}$

Carboxylic acids react with $\mathrm{LiAlH}_{4}$ which is a powerful reducing agent to give alcohols. Note that carboxylic acids and their derivatives are not reduced by $\mathrm{NaBH}_{4}$ which is a less powerful reducing agent than $\mathrm{LiAlH}_{4}$.

### 3.6 Reactions of carboxylic acid derivatives

It is instructive to compare the reactions of carboxylic acid derivatives and carboxylic acids with those of aldehydes and ketones (Figure 3.7).

carboxylic acids and acid derivatives nucleophilic substitution

$\mathrm{Z}=\mathrm{H}$; aldehyde
Z = alkyl or aryl; ketone
$\mathrm{Z}=\mathrm{OH}$; carboxylic acid
Z = Cl; acid chloride
$\mathrm{Z}=\mathrm{OR}$; ester
$\mathrm{Z}=\mathrm{NH}_{2}$; amide

Figure 3.7 Comparison of characteristic reactions of aldehydes/ ketones with those of carboxylic acids and their derivatives

The essential difference is that in contrast to aldehydes and ketones, the Z group in carboxylic acid derivatives and carboxylic acids is capable of behaving as a leaving group. That is in reactions involving heterolytic cleavage of $\mathrm{C}-\mathrm{Z}$ bond, Z leaves with the electron pair of the bond.

As in the case of aldehydes and ketones the first step of the reaction is the attack of a nucleophile on the carbonyl carbon of acids and acid derivatives with the opening of the carbon oxygen double bond to give a tetrahedral intermediate. This is followed by re-formation of the carbon oxygen double bond with the loss of Z as $\mathrm{Z}^{-}$under basic or neutral conditions or as ZH under acidic conditions.

Thus the carbon atom regains its trigonal geometry and the overall reaction is the substitution of Z with a nucleophile. This reaction pathway is not available in aldehydes and ketones as H , alkyl and aryl do not behave as leaving group.

### 3.6.1 Reactions of acid chlorides

### 3.6.1.1 Reaction with aqueous sodium hydroxide

Acid chlorides react with aqueous NaOH to form the corresponding carboxylic acid which reacts with excess NaOH to form its sodium salt.

The mechanism of the reaction is as follows.

In the above reaction the $\mathrm{OH}^{-}$is the nucleophile and $\mathrm{Cl}^{-}$is the leaving group.

### 3.6.1.2 Reaction with water

Acid chlorides react with water by a similar mechanism to form the corresponding carboxylic acid.

## G.C.E. (A/L) CHEMISTRY: UNIT 9

### 3.6.1.3 Reaction with alcohols and phenols

Acid chlorides react with alcohols and phenols to form alkyl esters and phenyl esters respectively.

### 3.6.1.4 Reaction with ammonia and primary amines

Acid chlorides react with ammonia to form primary amides.

Acid chlorides react with primary amines to form secondary amides.

Note: Amides are classified as primary amides when two $H$ atoms are attached to the $N$ atom. If one $H$ atom is replaced by an alkyl group, it is classified as a secondary amide and if both $H$ atoms are replaced by two alkyl groups the amide is classified as tertiary amide.

### 3.6.2 Reactions of esters

### 3.6.2.1 Reaction with dilute mineral acids

Esters react with dilute acids and give corresponding carboxylic acid and the alcohol as the products. In this reaction water acts as the nucleophile and the ester undergoes hydrolysis. This reaction also goes through the same tetrahedral intermediate involved in the formation of esters as given in Section 3.5.2.2 (b).

### 3.6.2.2 Reaction with aqueous sodium hydroxide

Esters when reacted with aqueous NaOH form the sodium salt of corresponding carboxylic acid and the alcohol. The mechanism of this reaction is similar to the mechanism of the reaction of acid chlorides with NaOH (Section 3.6.1.1).

## G.C.E. (A/L) CHEMISTRY: UNIT 9

### 3.6.2.3 Reaction with Grignard reagent

Esters react with Grignard reagents to give tertiary alcohols. In this reaction, the ester is first converted to a ketone which reacts rapidly with the Grignard reagent again to give the tertiary alcohol as the product.

Note that as ketones react faster than esters with Grignard reagents it is not possible to stop the reaction at the ketone stage.

### 3.6.2.4 Reduction by $\mathrm{LiAlH}_{4}$

Esters react with $\mathrm{LiAlH}_{4}$ and reduce to give alcohols.

### 3.6.3 Reactions of amides

### 3.6.3.1 Reaction with aqueous sodium hydroxide

When amides are warmed with an aqueous solution of NaOH , the sodium salt of the corresponding carboxylic acid is formed with liberation of gaseous $\mathrm{NH}_{3}$.

### 3.6.3.2 Reduction with $\mathrm{LiAlH}_{4}$

Amides are reduced to the corresponding primary amine with $\mathrm{LiAlH}_{4}$.

## Introduction

Common organic compounds containing N includes amines and amides. Reactions of amides have been discussed under derivatives of carboxylic acids because of the presence of acyl group which are common to all derivatives of carboxylic acids. In this unit properties and reactions of amines in relation to their structures will be discussed. Amines can be defined as compounds where alkyl or aryl groups are attached to nitrogen in place of hydrogen atoms in ammonia.

### 4.1 Structure, properties and reactions of primary amines and aniline

### 4.1.1 Classification of amines

Unlike in alkyl halides and alcohols, amines are classified as primary, secondary and tertiary according to the number of alkyl or aryl groups attached to the hetero atom ( N in amines). The compounds in which an alkyl or an aryl group is attached in place of one of the three hydrogen atoms in ammonia are called primary amines. The compounds in which two groups, each of which could be an alkyl or aryl group are attached in place of two atoms of hydrogen in ammonia are called secondary amines and the compounds in which three such groups are attached in place of the three atoms of hydrogen are called tertiary amines.

methylamine (primary amine)

dimethylamine (secondary amine)

trimethylamine (tertiary amine)

The compounds in which at least one aryl group (aromatic ring) is attached to the nitrogen atom are called aromatic amines.

aniline (primary aromatic amine)

N -methylaniline secondary aromatic amine

The simplest aromatic amine is the one with $\mathrm{NH}_{2}$ attached to a benzene ring (aniline)

### 4.1.2 Reactivity of the benzene ring of aniline

Similar to phenol, aniline readily reacts with bromine to give 2,4,6-tribromoaniline because the $-\mathrm{NH}_{2}$ group activates the benzene ring towards electrophilic substitution.

When this reaction is carried out with bromine water 2,4,6-tribromoaniline is observed as a white precipitate.

### 4.1.3 Reactions of primary amines

Amines can act as nucleophiles as the N atom contains a lone pair of electrons. The following are some of the reactions of primary amines with various reagents where the amine acts as a nucleophile.

### 4.1.3.1 Reaction of amines with alkyl halides

Primary amines react with alkyl halides to give secondary amines.

These secondary amines too have a lone pair of electrons on N atom and hence can further react with alkyl halide to form tertiary amines. Thus formed tertiary amine can react with alkyl halide further, because it also has a lone pair of electrons, to give a quaternary ammonium salt.

Therefore the reaction between primary amine and alkyl halides give a mixture of products.

### 4.1.3.2 Reaction of amines with aldehydes and ketones

Amines show nucleophilic addition followed by elimination with aldehydes and ketones. The products are called imines.

This reaction corresponds to the reaction of aldehydes and ketones with the 2,4-dinitrophenylhydrazine (Brady reagent).

### 4.1.3.3 Reaction of amines with acid chlorides

Primary amines react with acid chlorides to give secondary amides.

## G.C.E. (A/L) CHEMISTRY: UNIT 10 Nitrogen Containing Organic Compounds

### 4.1.3.4 Reaction of amines with nitrous acid $\left(\mathrm{NaNO}_{2} / \mathbf{H C l}\right)$

Primary amines react with nitrous acid to form diazonium salts. As alkyl diazonium salts are unstable they rapidly convert to alcohols with the evolution of nitrogen gas.

Aromatic diazonium salts formed from aromatic amines are more stable than alkyl diazonium salts.Therefore solutions of aromatic diazonium salts may be obtained at low temperatures.

### 4.2 Basicity of amines

Aliphatic amines are basic and the basicity is comparable to that of ammonia. Aqueous mineral acids or carboxylic acids convert amines into their salts. These salts react readily with hydroxide ions to regenerate the amine.

### 4.2.1 Basicity of amines versus alcohols

Nitrogen is less electronegative than oxygen. Therefore it has a higher tendency to donate lone pair of electrons than oxygen. On the other hand, nitrogen atom can bear a positive charge more easily than oxygen due to its lower electronegativity when compared to oxygen. Therefore the stability of the alkyl ammonium ion relative to the amine is more than the stability of the alkyl oxonium ion relative to the alcohol. Hence, amines are more basic than alcohols.

### 4.2.2 Basicity of primary aliphatic amines and aniline

Aliphatic primary amines are more basic than aniline. In aniline the lone pair of electrons on the nitrogen is delocalized on to the aromatic ring by resonance (Figure 4.1). Therefore it is not easily available to a proton. Due to this reason aniline show lower basicity than primary aliphatic amines.

Figure 4.1 Resonance structures of aniline

### 4.2.3 Basicity of amines compared to amides

Amides are less basic than amines. It is because the pair of electrons on the nitrogen of the amide group is delocalized on to the carbonyl group by resonance (Figure 4.2) making them less available to a proton than is the lone pair of electrons on the N atom of amines.

Figure 4.2 Resonance structures of amides

### 4.3 Reactions of aromatic diazonium salts

Aromatic amines such as aniline when reacted with nitrous acid $\left(\mathrm{NaNO}_{2} / \mathrm{HCl}\right)$ give aromatic diazonium salts which undergo decomposition at room temperature to give phenols.

Aromatic diazonium salts are more stable than aliphatic diazonium salts. Therefore, when this reaction is carried out at low temperatures, the conversion of the aromatic diazonium salt to the phenol can be slowed down, and the diazonium salt can be isolated.

Therefore aromatic diazonium salts are prepared by the treatment of aromatic primary amines with an aqueous solution of $\mathrm{NaNO}_{2}$ in the presence of dilute mineral acid such as dil. HCl or dil. $\mathrm{H}_{2} \mathrm{SO}_{4}$ at low temperature $\left(0-5^{\circ} \mathrm{C}\right)$. Since diazonium salts slowly decompose even at these temperatures, the solutions of diazonium salts are used immediately after preparation for any desired reaction.

Diazonium salts undergo a large number of reactions. They can be divided into two classes: replacement of the diazonium group by another atom or a group; and coupling in which diazonium ion act as an electrophile and the nitrogen atoms are retained in the product.

## G.C.E. (A/L) CHEMISTRY: UNIT 10

### 4.3.1 Reactions in which the diazonium group is replaced by another atom or a group

### 4.3.1.1 Reaction of diazonium salts with water

When aqueous solutions of diazonium salts are heated, phenols are formed.

### 4.3.1.2 Reaction of diazonium salts with hypophosphorous acid $\left(\mathbf{H}_{3} \mathrm{PO}_{2}\right)$

When diazonium salts are treated with hypophosphorous acid $\left(\mathrm{H}_{3} \mathrm{PO}_{2}\right)$, the diazonium group is replaced by an H atom.

### 4.3.1.3 Reaction of diazonium salts with CuCl and CuBr

When diazonium salts are reacted with CuCl or CuBr , the corresponding aromatic halide is formed. This reaction can also be carried out with copper powder and hydrogen halide $(\mathrm{Cu} / \mathrm{HCl}$ or HBr$)$ instead of copper(I) halide.

### 4.3.1.4 Reaction of diazonium salts with CuCN

When diazonium salts are reacted with CuCN , the diazonium group is replaced by CN group.

### 4.3.1.5 Reaction of diazonium salts with KI

When diazonium salts are reacted with KI, the diazonium group is replaced by I.

### 4.3.2 Reactions in which the diazonium ion acts as an electrophile

Aryl diazonium ions can participate as electrophiles as it contains a positive charge on N . They react with phenols under alkaline conditions.

Benzene diazonium chloride reacts with phenol in the presence of aqueous NaOH to give an orange coloured compound, and with $\beta$-naphthol (2-naphthol) in the presence of aqueous NaOH to give a red coloured compound.

orange

## Message from the Director General

The National Institute of Education takes opportune steps from time to time for the development of quality in education. Preparation of supplementary resource books for respective subjects is one such initiative.

Supplementary resource books have been composed by a team of curriculum developers of the National Institute of Education, subject experts from the national universities and experienced teachers from the school system. Because these resource books have been written so that they are in line with the G. C. E. (A/L) new syllabus implemented in 2017, students can broaden their understanding of the subject matter by referring these books while teachers can refer them in order to plan more effective learning teaching activities.

I wish to express my sincere gratitude to the staff members of the National Institute of Education and external subject experts who made their academic contribution to make this material available to you.

Dr. (Mrs.) T. A. R. J. Gunasekara<br>Director General<br>National Institute of Education<br>Maharagama.

## Message from the Director

Since 2017, a rationalized curriculum, which is an updated version of the previous curriculum is in effect for the G.C.E (A/L) in the general education system of Sri Lanka. In this new curriculum cycle, revisions were made in the subject content, mode of delivery and curricular materials of the G.C.E. (A/L) Physics, Chemistry and Biology. Several alterations in the learning teaching sequence were also made. A new Teachers' Guide was introduced in place of the previous Teacher's Instruction Manual. In concurrence to that, certain changes in the learning teaching methodology, evaluation and assessment are expected. The newly introduced Teachers' Guide provides learning outcomes, a guideline for teachers to mould the learning events, assessment and evaluation.

When implementing the previous curricula, the use of internationally recognized standard textbooks published in English was imperative for the Advanced Level science subjects. Due to the contradictions of facts related to the subject matter between different textbooks and inclusion of the content beyond the limits of the local curriculum, the usage of those books was not convenient for both teachers and students. This book comes to you as an attempt to overcome that issue.

As this book is available in Sinhala, Tamil, and English, the book offers students an opportunity to refer the relevant subject content in their mother tongue as well as in English within the limits of the local curriculum. It also provides both students and teachers a source of reliable information expected by the curriculum instead of various information gathered from the other sources.

This book authored by subject experts from the universities and experienced subject teachers is presented to you followed by the approval of the Academic Affairs Board and the Council of the National Institute of Education. Thus, it can be recommended as a material of high standard.

### 1.11 Energy profiles of reactions

## Introduction

In the previous units for example, unit 4 and 5 described the basic aspects of behavior of molecules depending on their physical state and energy requirements for the reaction to occur. Though, we know that the amounts of reactants and products and their molecular nature yet, we have not focused quantitatively on "How fast is the reaction proceed" and requirements to be satisfied to occur a chemical reaction. In this regard the present unit addresses and focuses on the field of kinetics where the rates of reactions are concerned. We examine the rate of a reaction, the factors that affect it, the theories that explain those effects, and the stepwise changes reactants undergo as they transform into products. This unit also introduce some general ideas about reaction rates and overview key factors that affect them-concentration/ pressure, physical state, catalyst and temperature. Further, express rate through a rate law and determine its components and see how concentrations change as a reaction proceeds and discuss the meaning of half-life. In addition, we discuss about reaction mechanisms, noting the steps a reaction goes through and picturing the chemical species that exists as reactant bonds are breaking and product bonds are forming.

### 1.1 Concept of chemical kinetics

We have gained some idea about chemical reactions in unit 5 (energetics). Chemistry is mainly concerned with changes occurring in nature or in substances of interest. Such changes are depicted in a simple way by an equation which is considered a chemical reaction. In the study of any chemical reaction we try to find out the followings.
(a) The feasibility of a chemical reaction, which can be predicted by thermodynamics. For example, energy changes associated with a reaction are expressed by thermodynamic quantities such as $\Delta H, \Delta G, \Delta S$ and we know that a reaction with $\Delta G<0$, at constant temperature and pressure is feasible. This also gives us in which direction the reaction occurs.
(b) Extent of a reaction, which explains how far a reaction proceeds to give the desired products and this can be determined from chemical equilibrium (unit 12). This can be quantified with the knowledge of the equilibrium constant.

Along with these, there is another equally important aspect for a given reaction worth paying attention; that is how fast a reaction occurs or the rate of a reaction and factors controlling the rate of a reaction. In this case, time taken by a reaction to reach some known point (extent) has to be studied. Further, how the conversion of reactants to products occurs: that is the mechanism of the reaction has to be known. All these questions can be answered by a branch of chemistry, which deals with the study of reaction rates and their mechanisms, called "chemical kinetics".

If a reaction is to occur, it must be both thermodynamically and kinetically favoured under given conditions such as temperature and pressure of the system. These are relative terms: the reaction must be thermodynamically favoured enough to form the amount of the product desired, and it must be kinetically favoured enough to be completed within the
desired time period. For example, nuclear reactions occur very fast (in a fraction of a second) and the conversion of graphite to diamond takes millions of years. This is because it has an enormous activation energy that must be overcome before the reaction may proceed. We must also consider the mechanism of the reaction which is a sequence of events at the molecular level that controls the speed and the desired products of the reaction. Therefore, studying the rates of reactions is very important in many fields. These factors of thermodynamics and kinetics can be simply shown schematically in Figure 1.1 below.

Figure 1.1 Controlling chemical reactions in view of thermodynamics and kinetics

Kinetic studies not only help us to determine the speed or rate of a chemical reaction but also describe the conditions which can alter the reaction rates. The factors such as concentration, temperature, pressure and catalyst affect the rate of a reaction. In these studies, investigations in measurable quantities such as amounts reacted or formed and the rates of consumption or formation come under macroscopic level. At the molecular level, the reaction mechanisms involving orientation, velocities and energy of molecules undergoing collisions have to be considered. These parameters are somewhat hard to measure.

When we consider chemical processes, many chemical processes such as explosive reactions take place in a fraction of a second while the rusting of iron may take a very long time, sometimes in centuries for completion. Ionic reactions in solution, for example the reaction between $\mathrm{NaCl}(\mathrm{aq})$ and $\mathrm{AgNO}_{3}(\mathrm{aq})$ giving a white precipitate of silver chloride occurs within a very short (but measurable with some advanced techniques) time. In chemical kinetics, at this stage we actually study the rates of reactions which are neither so fast nor so slow. Usually, a chemical reaction involves breaking of bonds in the reactant molecules and making of bonds in the product molecules and it is easy to understand that a reaction that involves breaking of weak bond(s) is faster than a one involving breaking of strong bond(s) at a given temperature. Ionic compounds such as strong electrolytes in solution remain completely ionized and hence in any ionic reaction, no bond is broken. Therefore, an ionic reaction is fast. Different reactions, as they involve variety of bonding in respect of the strength of the bonds to be broken, occur at different rates. Reactions which involve less bond rearrangements are generally faster than those which involve considerable bond rearrangements at a given temperature. Chemical kinetics or reaction kinetics is the study of rates of chemical processes. Chemical kinetics includes
investigations of how different experimental conditions can influence the speed of a chemical reaction and gives information about the mechanisms of reactions and transition states, as well as the construction of mathematical models (rate equations) that can describe the characteristics of a chemical reaction. With this it may worth to categorize reactions with respect to their rates as described below.

## Very fast (Instantaneous) reactions

These reactions are so fast and occur as soon as the reactants are bought together. These reactions involve ionic species and are thus known as ionic reactions. There are many reactions occurring on the surfaces of catalysts. They are much faster and usually take place in $10^{-12}$ to $10^{-18}$ seconds in the time scale. It is almost impossible to determine the rates of these reactions with conventional techniques. However, there are advanced techniques available with ultra-fast laser spectroscopy which in further allow us even to follow electron transfer processes. Some examples we can consider for these very fast reactions are;

Formation of a precipitate of AgCl when highly concentrated solutions of silver nitrate and sodium chloride are mixed:

$$
\mathrm{AgNO}_{3}(\mathrm{aq})+\mathrm{NaCl}(\mathrm{aq}) \longrightarrow \mathrm{AgCl}(\mathrm{~s})+\mathrm{NaNO}_{3}(\mathrm{aq})
$$

Neutralisation of a strong acid with a strong base when their aqueous solutions are mixed:

$$
\mathrm{HCl}(\mathrm{aq})+\mathrm{NaOH}(\mathrm{aq}) \longrightarrow \mathrm{NaCl}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

## Very slow reactions

There are certain reactions which occur in extremely slow rates or sometimes never happen at the room temperature. It is therefore, difficult to study the kinetics of such reactions. Examples:

Reaction between hydrogen and oxygen at room temperature: This is highly explosive at high temperatures $(\sim 1000 \mathrm{~K})$.
Reaction between carbon and oxygen; coke does not catch fire spontaneously in air and remains unreacted.

## Moderate reactions

Between the above two extremes, there is a large number of reactions which take place at moderate and measurable rates at room temperature and these allow us to study chemical kinetics under laboratory conditions. Some common examples are given below.

Decomposition of hydrogen peroxide:

$$
2 \mathrm{H}_{2} \mathrm{O}_{2}(\mathrm{aq}) \rightarrow 2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})+\mathrm{O}_{2}(\mathrm{~g})
$$

Decomposition of nitrogen pentoxide:

$$
2 \mathrm{~N}_{2} \mathrm{O}_{5}(\mathrm{~g}) \rightarrow 2 \mathrm{~N}_{2} \mathrm{O}_{4}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g})
$$

Hydrolysis of an ester:

$$
\mathrm{CH}_{3} \mathrm{COOC}_{2} \mathrm{H}_{5}(\mathrm{aq})+\mathrm{NaOH}(\mathrm{aq}) \rightarrow \mathrm{CH}_{3} \mathrm{COONa}(\mathrm{aq})+\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(\mathrm{aq})
$$

## G.C.E. (A/L) CHEMISTRY: UNIT 11 Chemical Kinetics

Inversion of sucrose in aqueous solution:

$$
\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightarrow \mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}(\mathrm{aq})+\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}(\mathrm{aq})
$$

Reaction between nitrogen dioxide and carbon monoxide:

$$
\mathrm{NO}_{2}(\mathrm{~g})+\mathrm{CO}(\mathrm{~g}) \rightarrow \mathrm{NO}(\mathrm{~g})+\mathrm{CO}_{2}(\mathrm{~g})
$$

Reaction between nitric acid and thiosulfate:

$$
\mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}(\mathrm{aq})+2 \mathrm{HNO}_{3}(\mathrm{aq}) \rightarrow \mathrm{S}(\mathrm{~s})+2 \mathrm{NaNO}_{3}(\mathrm{aq})+\mathrm{SO}_{2}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

Reaction between ferric chloride and potassium iodide:

$$
2 \mathrm{I}^{-}(\mathrm{aq})+2 \mathrm{Fe}^{3+}(\mathrm{aq}) \rightarrow \mathrm{I}_{2}(\mathrm{aq})+2 \mathrm{Fe}^{2+}(\mathrm{aq})
$$

Reaction between calcium carbonate and hydrochloric acid:

$$
\mathrm{CaCO}_{3}(\mathrm{~s})+2 \mathrm{HCl}(\mathrm{aq}) \rightarrow \mathrm{CaCl}_{2}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})+\mathrm{CO}_{2}(\mathrm{~g})
$$

The rates of chemical processes can be decreased or increased by changing conditions under which they occur. For example, very slow reaction at room temperature; $\mathrm{CO}+2 \mathrm{H}_{2} \rightarrow \mathrm{CH}_{3} \mathrm{OH}$, can be speeded up by maintaining temperature around $400{ }^{\circ} \mathrm{C}$, pressure about 300 atm and using a catalyst. The decay of food items can be slowed down by reserving them in refrigerators.

In the study of chemical kinetics, we can predict the rate of a particular reaction under given conditions and that conditions can be adjusted or optimized to make the reactions occur at a desired rate. This is useful in industry to accelerate the formation of industrial products and to predict the mechanism of the reaction.

### 1.2 Rate of a reaction

Different reactions can occur at different rates. Reactions that occur slowly have a low rate of reaction and reactions that occur quickly have a high rate of reaction. As mentioned above, for example, the chemical change of graphite to diamond and weathering of rocks are very slow reactions; it has a low rate of reaction. Explosions and nuclear reaction are very fast reactions: they have a high rate of reaction.

In general, a reaction can be represented as follows.

$$
\text { Reactants } \rightarrow \text { Products }
$$

When the reaction proceeds, reactants are consumed while products are formed. As a result, the speed of a reaction or the rate of a reaction can be defined as the change in amount (concentration) of a reactant or product in unit time. That is;
(i) the rate of decrease in amount/ concentration of any one of the reactants, or
(ii) the rate of increase in amount/ concentration of any one of the products at a constant temperature.

Consider a hypothetical reaction at a constant temperature and also assume that the volume of the system remains constant.

$$
\mathrm{A} \rightarrow \mathrm{~B}
$$

In general, it is more convenient to express the reaction rate in terms of the change in amount with time at a constant temperature. For the reaction above let's consider that at the time $\boldsymbol{t}_{\boldsymbol{i}}\left(\right.$ not at $t=0$ ) the initial amount of A is $\left(\boldsymbol{n}_{A}\right)_{i}$ moles and after some time $\boldsymbol{t}_{\boldsymbol{t}}$, the amount of A is $\left(\boldsymbol{n}_{A}\right)_{t}$ moles. Therefore, the change in amount of A within the time interval $\left(\boldsymbol{t}_{\boldsymbol{t}}-\boldsymbol{t}_{\boldsymbol{i}}\right)$ is $\left[\left(\boldsymbol{n}_{A}\right)_{\boldsymbol{t}}-\left(\boldsymbol{n}_{A}\right)_{i}\right]$ moles.
$\therefore$ The rate of change in the amount of $\mathrm{A}=\frac{\left[\left(n_{A}\right) t^{-}\left(n_{A}\right)_{i}\right]}{t_{t}-t_{i}}=\frac{\Delta\left(n_{A}\right)}{\Delta t}$

Similarly for the product B we can write,
The rate of change in amount of B

$$
=\frac{\left[\left(n_{B}\right)_{t}-\left(n_{B}\right)_{i}\right]}{t_{t}-t_{i}}=\frac{\Delta\left(n_{B}\right)}{\Delta t}
$$

In the above, $\Delta\left(n_{A}\right)$; change in amount of the reactant has a negative sign because $\left(n_{A}\right)_{t}<\left(n_{A}\right)_{i}$. It is important to note that the change in amount in any chemical process is considered to be a positive quantity. Hence in the case of change in amount in a reactant we use a negative sign. So, the rate of change in amount is always a positive quantity. Therefore, the rate of the above reaction can be written as,

$$
\text { Rate }=-\frac{\Delta\left(n_{A}\right)}{\Delta t}=\frac{\Delta\left(n_{B}\right)}{\Delta t}
$$

With the above understanding, the rate of a reaction can easily be correlated with the change in amount of either reactant(s) or product(s) of the reaction as the rate of consumption of the reactants or formation of the products.

In this simple description, the rate depends upon the change in amount of reactants or products and the time taken for that change to occur. Thus, the variation of the rate of the reaction $\mathrm{A} \rightarrow \mathrm{B}$ can be illustrated as shown in Figure 1.2.

Figure 1.2 The rate of reaction $\mathrm{A} \rightarrow \mathrm{B}$; is the decrease of $n_{\mathrm{A}}$ and increase of $n_{\mathrm{B}}$ with time at a constant temperature. It has to be noted that the rate of the reaction has decreased over the time.

In a mathematical point of view, this quantity $-\frac{\Delta\left(n_{A}\right)}{\Delta t}$ or $\frac{\Delta\left(n_{B}\right)}{\Delta t}$ can be represented as depicted in Figure 1.3(a) where the rate of the reaction is given by the change in amount
$\Delta\left(n_{A}\right)$ or $\Delta\left(n_{B}\right)$ over the time interval $\Delta t$ and usually this rate is defined as average rate. Usually the rate changes at a very small time and hence to calculate the rate over the time interval $\Delta t$, the rates at each time within the interval has to be averaged. The rate at a given instance of time is the slope of the tangent drawn to the curve showing the variation of amount with time as shown in Figures 1.3 (b) and (c) for the product B and reactant A, respectively. It is noted that the slope for the rate of change in amount of A (reactant) is negative indicating that the amount decreases with the time and therefore, we use a negative sign in front of the slope when the rate is calculated. It also shows that the rate also decreases with time as the slope decreases with the time because the reactant is consumed during the progress of reaction.

Figure 1.3 The rate of reaction $\mathrm{A} \rightarrow \mathrm{B}$; (a) Description of rate as the change in amount $\Delta \mathrm{n}$ over time period $\Delta \mathrm{t}$. The definition of rate as the slope of the tangent drawn to the curve showing the variation of amount of the product $B$ with time (b) and the reactant A with time (c). In (c), negative slope indicates that the amount of reactants is decreasing over the time. It is also shown in (b) and (c) that the rate of the reaction decreases with the time as the slope of the tangent decreases.

In the above we have gone through a very basic idea about the description of reaction rate in which the change in amount (number of moles) is considered the measure of the quantity. If we consider the volume of the container in which the reactions occurs as $V$ and it does not change during the progress of reaction then we can define the rate of the reaction as the change in amount of either reactant(s) or product(s) per unit time per unit volume. If the volume $V$ of the system in which the reaction is carrying out is constant, we can write the rate as,

$$
\text { Rate }=\frac{\Delta\left(n_{A}\right)}{V \Delta t}=\frac{\Delta\left(C_{A}\right)}{\Delta t} \quad \because \quad\left(n_{A}\right) / V=C_{A}: \text { concentration }
$$

Thus we can then express the rate of the reaction as the change in concentration of either reactant(s) or product(s) per unit time as: Rate $=-\frac{\Delta\left(C_{A}\right)}{\Delta t}=\frac{\Delta\left(C_{B}\right)}{\Delta t}$.

## G.C.E. (A/L) CHEMISTRY: UNIT 11 Chemical Kinetics

We can therefore, replace the amount in $y$-axis in the plots of Figures 1.2 and 1.3 with the concentration and hereafter, we use the concentration to represent the change in quantity of a given reaction as shown in Figure 1.4.

Figure 1.4 The rate of reaction $\mathrm{A} \rightarrow \mathrm{B}$; description of rate as the change in concentration over the time. Rate decreases with the time as is evident from the decrease in the slope of the curve.

We can also see in this plot that the reaction slows down as it proceeds (not the case with reactions) indicating that the reaction rate depends on the concentration of A available to react. Note that when [A] is large, the slope of the curve is steep and hence the reaction is fast. Later in the reaction, [A] is much smaller, and so is the slope. Hence the reaction slows down as A is used up showing that there is a concentration dependence of rate.

## Units of rate:

As the rate is defined as the change in concentration at a given time, the units will be $\mathbf{m o l} \mathbf{d m}^{-3} \mathbf{s}^{-1}$ (if the time is measured in seconds). This unit can easily be applied for the reactions in solutions. When the gas phase reactions are concerned we have to measure the concentrations as partial pressures. Therefore, the units will be $\mathbf{P a} \mathbf{s}^{-1}$ (or atm s${ }^{-1}$ ). It can further be understood that the reaction rate will be equal (proportional) to the reciprocal of time $(1 / t)$ if the time taken to occur a given change in a reaction is monitored. For a reaction $\mathrm{A} \rightarrow \mathrm{B}$, we write the rate as;

$$
\text { Rate }=-\frac{\Delta\left(C_{A}\right)}{\Delta t}=\frac{\Delta\left(C_{B}\right)}{\Delta t}
$$

If the change occurred is a constant and the time taken for that change is $t$, we write,

$$
\begin{gathered}
\text { Rate }=\frac{\text { constant }}{t} \\
\text { or } \\
\text { Rate } \alpha \frac{1}{t}
\end{gathered}
$$

## G.C.E. (A/L) CHEMISTRY: UNIT 11 Chemical Kinetics

### 1.3 Reaction rate and stoichiometry

As shown in section 1.2, the rate of a simple reaction of the type $A \rightarrow B$ at a constant temperature and in a closed rigid vessel (constant volume) can be expressed either as the rate of decrease in concentration of $\mathrm{A},-\frac{\Delta\left(C_{A}\right)}{\Delta t}$ or as the rate of increase in concentration of $\mathrm{B}, \frac{\Delta\left(C_{B}\right)}{\Delta t}$. In this reaction we see that one mole of A gives one mole of B , so that the rate can be given as are equal giving $-\frac{\Delta\left(C_{A}\right)}{\Delta t}=\frac{\Delta\left(C_{B}\right)}{\Delta t}$. Now let us consider a reaction when 2 moles of A giving one mole of B.

$$
2 \mathrm{~A} \rightarrow \mathrm{~B}
$$

Because two moles of A are consumed to produce one mole of B, the rate of consumption of A would be twice the rate of production of B. Therefore, we can express the rate of the reaction as;

$$
-\frac{1}{2} \frac{\Delta\left(C_{A}\right)}{\Delta t}=\frac{\Delta\left(C_{B}\right)}{\Delta t}
$$

Or we write the same as,

$$
-\frac{1}{2} \frac{\Delta[\mathrm{~A}]}{\Delta t}=\frac{\Delta[\mathrm{B}]}{\Delta t}
$$

Therefore, in general for a reaction: $a \mathrm{~A}+b \mathrm{~B} \rightarrow c \mathrm{C}+d \mathrm{D}$
We can write,

$$
\text { Rate }=-\frac{1}{a} \frac{\Delta[\mathrm{~A}]}{\Delta t}=-\frac{1}{b} \frac{\Delta[\mathrm{~B}]}{\Delta t}=\frac{1}{c} \frac{\Delta[\mathrm{C}]}{\Delta t}=\frac{1}{d} \frac{\Delta[\mathrm{D}]}{\Delta t}
$$

## Example 1.1

Consider the decomposition of $\mathrm{H}_{2} \mathrm{O}_{2}(\mathrm{aq})$ occurring in a $1.0 \mathrm{dm}^{3}$ rigid container at a given temperature according to the following reaction.

$$
2 \mathrm{H}_{2} \mathrm{O}_{2}(\mathrm{aq}) \rightarrow 2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})+\mathrm{O}_{2}(\mathrm{~g})
$$

Write the rate of the above reaction in terms of both reactants and products.

## Answer

Assuming that the reaction proceeds according to the stoichiometry as shown in the Figure 1.5, plot the variations in concentrations of each species in the reaction mixture over the time.
According to the stoichiometry of the reaction; 2 moles of $\mathrm{H}_{2} \mathrm{O}_{2}(\mathrm{aq})$ give 2 moles of $\mathrm{H}_{2} \mathrm{O}(\mathrm{l})$ and one mole of $\mathrm{O}_{2}(\mathrm{~g})$. As the volume of the container is $1.0 \mathrm{dm}^{3}$ :

Initial concentrations; $\mathrm{H}_{2} \mathrm{O}_{2}(\mathrm{aq}): \mathrm{H}_{2} \mathrm{O}(\mathrm{l}): \mathrm{O}_{2}(\mathrm{~g})=2.0: 0.0: 0.0 \mathrm{~mol} \mathrm{dm}^{-3}$
Final concentrations; $\mathrm{H}_{2} \mathrm{O}_{2}(\mathrm{aq}): \mathrm{H}_{2} \mathrm{O}(\mathrm{l}): \mathrm{O}_{2}(\mathrm{~g})=0.0: 2.0: 1.0 \mathrm{~mol} \mathrm{dm}^{-3}$

## G.C.E. (A/L) CHEMISTRY: UNIT 11 Chemical Kinetics

Figure 1.5 The variation of concentrations of the species in reaction

$$
2 \mathrm{H}_{2} \mathrm{O}_{2}(\mathrm{aq}) \rightarrow 2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})+\mathrm{O}_{2}(\mathrm{~g}) \text { at a given temperature }
$$

Rate of the reaction can be written as;

$$
\text { rate }=-\frac{1}{2} \frac{\Delta\left[\mathrm{H}_{2} \mathrm{O}_{2}\right]}{\Delta t}=\frac{1}{2} \frac{\Delta\left[\mathrm{H}_{2} \mathrm{O}\right]}{\Delta t}=\frac{\Delta\left[\mathrm{O}_{2}\right]}{\Delta t} \text { or } \frac{-\Delta\left[\mathrm{H}_{2} \mathrm{O}_{2}\right]}{\Delta t}=\frac{\Delta\left[\mathrm{H}_{2} \mathrm{O}\right]}{\Delta t}=2 \frac{\Delta\left[\mathrm{O}_{2}\right]}{\Delta t}
$$

It has to be noted that the above graphs were drawn with the accurate scale according to the stoichiometry and rate of the reaction. Therefore, from the plots after time $t$ the rates (slopes) can be calculates as:
$-\frac{\Delta\left[\mathrm{H}_{2} \mathrm{O}_{2}\right]}{\Delta t}=-\frac{(-) 2 x}{t}=\frac{2 x}{t} ; \frac{\Delta\left[\mathrm{H}_{2} \mathrm{O}\right]}{\Delta t}=\frac{2 x}{t}$ and $\frac{\Delta\left[\mathrm{O}_{2}\right]}{\Delta t}=\frac{x}{t}$
This clearly implies the definition of the rate of this reaction. Therefore, we can understand that the rates of reactions can be experimentally determined or estimated.

## Example 1.2

Write the rates of following reactions in terms of both reactants and products.
(i) $\quad \mathrm{Na}_{2} \mathrm{CO}_{3}(\mathrm{aq})+2 \mathrm{HCl}(\mathrm{aq}) \rightarrow 2 \mathrm{NaCl}(\mathrm{aq})+\mathrm{CO}_{2}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{O}$ (l)
(ii) $\quad \mathrm{N}_{2}(\mathrm{~g})+3 \mathrm{H}_{2}(\mathrm{~g}) \rightarrow 2 \mathrm{NH}_{3}(\mathrm{~g})$

## Answer

$$
\begin{equation*}
\text { Rate }=-\frac{\Delta\left[\mathrm{Na}_{2} \mathrm{CO}_{3}(\mathrm{aq})\right]}{\Delta t}=-\frac{1}{2} \frac{\Delta[\mathrm{HCl}]}{\Delta t}=\frac{1}{2} \frac{\Delta[\mathrm{NaCl}]}{\Delta t}=\frac{\Delta\left[\mathrm{CO}_{2}(\mathrm{~g})\right]}{\Delta t} \tag{i}
\end{equation*}
$$

(ii) Rate $=-\frac{\Delta\left[\mathrm{N}_{2}(\mathrm{~g})\right]}{\Delta t}=-\frac{1}{3} \frac{\Delta\left[\mathrm{H}_{2}(\mathrm{~g})\right]}{\Delta t}=\frac{1}{2} \frac{\Delta\left[\mathrm{NH}_{3}\right]}{\Delta t}$

## Example 1.3

$\mathrm{N}_{2} \mathrm{O}_{5}(\mathrm{~g})$ decomposes as follows:

$$
2 \mathrm{~N}_{2} \mathrm{O}_{5}(\mathrm{~g}) \rightarrow 4 \mathrm{NO}_{2}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g})
$$

It was found that in a closed rigid vessel at a particular instant the rate of decomposition of $\mathrm{N}_{2} \mathrm{O}_{5}(\mathrm{~g})$ was $3.0 \times 10^{-7} \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{~s}^{-1}$ at a constant temperature. Write the rates of formation of (i) $\mathrm{NO}_{2}(\mathrm{~g})$ and (ii) $\mathrm{O}_{2}(\mathrm{~g})$.

## Answer

We can write the rate of the reaction as;

$$
\text { Rate }=-\frac{1}{2} \frac{\Delta\left[\mathrm{~N}_{2} \mathrm{O}_{5}(\mathrm{~g})\right]}{\Delta t}=\frac{1}{4} \frac{\Delta\left[\mathrm{NO}_{2}(\mathrm{~g})\right]}{\Delta t}=\frac{\Delta\left[\mathrm{O}_{2}(\mathrm{~g})\right]}{\Delta t}
$$

(i)

$$
\begin{aligned}
& \frac{1}{2} \times 3.0 \times 10^{-7} \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{~s}^{-1}=\frac{1}{4} \frac{\Delta\left[\mathrm{NO}_{2}(\mathrm{~g})\right]}{\Delta t} \\
& \frac{\Delta\left[\mathrm{NO}_{2}(\mathrm{~g})\right]}{\Delta t}=6.0 \times 10^{-7} \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{~s}^{-1}
\end{aligned}
$$

(ii)

$$
\begin{aligned}
& \frac{1}{2} \times 3.0 \times 10^{-7} \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{~s}^{-1}=\frac{\Delta\left[\mathrm{O}_{2}(\mathrm{~g})\right]}{\Delta t} \\
& \frac{\Delta\left[\mathrm{O}_{2}(\mathrm{~g})\right]}{\Delta t}=1.5 \times 10^{-7} \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{~s}^{-1}
\end{aligned}
$$

## Example 1.4

In the reaction taking place in a closed rigid container at a constant temperature:

$$
2 \mathrm{NOBr}(\mathrm{~g}) \rightarrow 2 \mathrm{NO}(\mathrm{~g})+\mathrm{Br}_{2}(\mathrm{~g})
$$

the rate of formation of $\mathrm{NO}(\mathrm{g})$ was found to be $2.0 \times 10^{-4} \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{~s}^{-1}$.
Write the rates of (i) the reaction and (ii) the consumption of $\operatorname{NOBr}(\mathrm{g})$.

## Answer

We can write; Rate $=-\frac{1}{2} \frac{\Delta[\mathrm{NOBr}(\mathrm{g})]}{\Delta t}=\frac{1}{2} \frac{\Delta[\mathrm{NO}(\mathrm{g})]}{\Delta t}=\frac{\Delta\left[\mathrm{Br}_{2}(\mathrm{~g})\right]}{\Delta t}$
(i) $\quad \therefore$ rate of the reaction $=\frac{1}{2} \times 2.0 \times 10^{-4} \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{~s}^{-1}$

$$
=1.0 \times 10^{-4} \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{~s}^{-1}
$$

(ii) $\frac{1}{2} \frac{\Delta[\operatorname{NOBr}(\mathrm{~g})]}{\Delta t}=1.0 \times 10^{-4} \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{~s}^{-1}$

$$
\therefore \frac{\Delta[\operatorname{NOBr}(\mathrm{g})]}{\Delta t}=2.0 \times 10^{-4} \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{~s}^{-1}
$$

## Example 1.5

At a given time, the rate of the following reaction with respect to $\mathrm{C}_{2} \mathrm{H}_{4}$ is $0.20 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{~s}^{-1}$. Write the rate of the reaction with respect other species in the reaction.

$$
\mathrm{C}_{2} \mathrm{H}_{4}(\mathrm{~g})+3 \mathrm{O}_{2}(\mathrm{~g}) \rightarrow 2 \mathrm{CO}_{2}(\mathrm{~g})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{~g})
$$

## Answer

Rate of the reaction:

$$
\text { Rate }=-\frac{\Delta\left[\mathrm{C}_{2} \mathrm{H}_{4}(\mathrm{~g})\right]}{\Delta t}=-\frac{1}{3} \frac{\Delta\left[\mathrm{O}_{2}(\mathrm{~g})\right]}{\Delta t}=\frac{1}{2} \frac{\Delta\left[\mathrm{CO}_{2}(\mathrm{~g})\right]}{\Delta t}=\frac{1}{2} \frac{\Delta\left[\mathrm{H}_{2} \mathrm{O}(\mathrm{~g})\right]}{\Delta t}
$$

Given that, $\frac{\Delta\left[\mathrm{C}_{2} \mathrm{H}_{4}(\mathrm{~g})\right]}{\Delta t}=0.20 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{~s}^{-1}$

$$
\begin{aligned}
& \frac{\Delta\left[\mathrm{O}_{2}(\mathrm{~g})\right]}{\Delta t}=3 \times \frac{\Delta\left[\mathrm{C}_{2} \mathrm{H}_{4}(\mathrm{~g})\right]}{\Delta t}=3 \times 0.20 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{~s}^{-1}=0.60 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{~s}^{-1} \\
& \frac{\Delta\left[\mathrm{CO}_{2}(\mathrm{~g})\right]}{\Delta t}=2 \times \frac{\Delta\left[\mathrm{C}_{2} \mathrm{H}_{4}(\mathrm{~g})\right]}{\Delta t}=2 \times 0.20 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{~s}^{-1}=0.40 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{~s}^{-1} \\
& \frac{\Delta\left[\mathrm{H}_{2} \mathrm{O}(\mathrm{~g})\right]}{\Delta t}=2 \times \frac{\Delta\left[\mathrm{C}_{2} \mathrm{H}_{4}(\mathrm{~g})\right]}{\Delta t}=2 \times 0.20 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{~s}^{-1}=0.40 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{~s}^{-1}
\end{aligned}
$$

From the above examples we can see that the rate of a reaction is not directly equal to either the rate of disappearance of reactants or the rate of appearance of products.

Therefore, for a reaction taking place at constant temperature and constant volume, rate of the reaction is given by;

$$
\text { Rate }=\frac{1}{v_{\mathrm{j}}} \frac{\Delta[\mathrm{~J}]}{\Delta t}
$$

$\boldsymbol{v}_{\boldsymbol{j}}$ is the stoichiometric coefficient of the substance $\boldsymbol{J} . \boldsymbol{v}_{\boldsymbol{j}}$ is negative for reactants and positive for products.

## Example 1.6

Consider the reaction, $\mathrm{A} \rightarrow 2 \mathrm{~B}$, which was started with the initial concentration of $0.50 \mathrm{~mol} \mathrm{dm}^{-3}$ of reactant A . It drops to $0.00 \mathrm{~mol} \mathrm{dm}^{-3}$ in 10 seconds. During this time the concentration of B increased from $0.00 \mathrm{~mol} \mathrm{dm}^{-3}$ to $1.00 \mathrm{~mol} \mathrm{dm}^{-3}$. Calculate the rate of this reaction as follows.

## Answer

We can write the rate of the reaction as; Rate $=\frac{1}{v_{j}} \frac{\Delta[\mathrm{~A}]}{\Delta t}=-\frac{\Delta[\mathrm{A}]}{\Delta t}$

$$
\begin{aligned}
& =-\frac{(0.00-0.50) \mathrm{mol} \mathrm{dm}^{-3}}{10 \mathrm{~s}} \\
& =0.05 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{~s}^{-1}
\end{aligned}
$$

or

$$
\begin{aligned}
\text { Rate } & =\frac{1}{v_{\mathrm{j}}} \frac{\Delta[\mathrm{~B}]}{\mathrm{d} t}=\frac{1}{2} \frac{\Delta[\mathrm{~B}]}{\Delta t}=\frac{1}{2} \times \frac{(1.00-0.00) \mathrm{mol} \mathrm{dm}^{-3}}{10 \mathrm{~s}} \\
& =0.05 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{~s}^{-1}
\end{aligned}
$$

## Example 1.7

The decomposition of A at 300 K in a solution with constant volume can be followed by monitoring the concentration of A. Initially (at $t=0$ ), the concentration of $A$ is $2.00 \mathrm{~mol} \mathrm{dm}^{-3}$ and after 180 seconds, it is reduced to $1.64 \mathrm{~mol} \mathrm{dm}^{-3}$. The reaction takes place according to the equation

$$
2 \mathrm{~A}(\mathrm{aq}) \rightarrow 4 \mathrm{~B}(\mathrm{aq})+\mathrm{C}(\mathrm{aq})
$$

Calculate the rate of this reaction.

## Answer

$\Delta \mathrm{A}=1.64-2.00=-0.36 \mathrm{~mol} \mathrm{dm}^{-3}$
$\therefore-\Delta \mathrm{A}=0.36 \mathrm{~mol} \mathrm{dm}^{-3}$
According to the reaction,

$$
\begin{aligned}
\text { Rate }=1 / 2[\Delta[\mathrm{~A}] / \Delta t] & =1 / 2 \times 0.36 \mathrm{~mol} \mathrm{dm}^{-3} / 180 \mathrm{~s} \\
& =1.0 \times 10^{-3} \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{~s}^{-1}
\end{aligned}
$$

## G.C.E. (A/L) CHEMISTRY: UNIT 11 <br> Chemical Kinetics

### 1.4 Experimental techniques to determine the rates of reactions

As from the example 1.1 and other calculations, we know that the reaction rates are experimentally determined quantities and therefore it is necessary to understand that how the rate of a reaction, is obtained experimentally. In this context, we know to determine the rate of a reaction we have to monitor the concentration of the reactant (or product) as a function of time. That is, in order to determine the rate of a particular reaction, it is necessary to follow either the rate of decrease in concentration of a reactant(s), or the rate of increase in concentration of a product, by choosing an appropriate experimental method at a constant temperature. We can categorize the techniques as non-disruptive and disruptive. In non-disruptive techniques, this is done through a measurement of a rapidly determinable physical property of the reaction mixture. For example, for reactions in solutions, the concentration of a species can often be measured by spectrophotometric techniques if coloured species are involved. If ions are involved, the change in concentration can also be detected by an electrical conductance measurement. Reactions involving gases are monitored by pressure measurements under the constant volume.

## Spectrophotometric methods

This is usually employed when at least one of the species involved in the reaction is coloured and its absorbance is monitored as a function of time at a suitable wavelength obtained from the absorption spectrum of either a reactant or a product. As the absorbance is directly proportional to the concentration of the particular species, the rate of the reaction can be monitored by these absorbance measurements as a function of time.

## Methods involving the measurement of change in total pressure

As we know, the total pressure of a gas-phase reaction occurring in rigid container at any time will be the sum of the partial pressures of all the gaseous reactants and products. Thus if the stoichiometry of the reaction is known, this can be used to determine either the rate of decrease of a reactant or the rate of increase of a product as a function of the measured total pressure.

## Electrical conductance/ conductivity method

Consider, for example, the reaction:

$$
\mathrm{R}_{1} \mathrm{COOR}_{2}(\mathrm{aq})+\mathrm{OH}^{-}(\mathrm{aq}) \rightarrow \mathrm{R}_{1} \mathrm{COO}^{-}(\mathrm{aq})+\mathrm{R}_{2} \mathrm{OH}(\mathrm{aq})
$$

The conductivity of hydroxyl ions is much higher than that of the other ions such as ethanoate ions ( $\mathrm{R}_{1}=\mathrm{C}_{2} \mathrm{H}_{5}$ ). Also the conductivity depends on the concentration of ions and hence, measurement of the conductance is an appropriate method for following the rate of loss of hydroxyl ions in the above process where the decrease in conductivity will be observed.

## G.C.E. (A/L) CHEMISTRY: UNIT 11 Chemical Kinetics

## Optical rotation method

This method is suitable for reactions where the optical activity of the products is different from those of the reactants. For example hydrolysis of sucrose gives glucose and fructose with different optical rotations. An instrument called "polarimeter" is used for the optical rotation measurements. As the optical rotation is related to the concentration, measurement of the optical rotation will then be related to the rate of the reaction.

## Refractive index method

This method is especially useful for liquid-phase reactions where the refractive index of reaction mixture changes in the course of the reaction due to increase in the products and decrease in the reactants.

## Gas evolution method

If there is one gaseous product in a reaction, the gas evolved can be collected and its volume measured as a function of time. For example, the decomposition of calcium carbonate proceeds by producing $\mathrm{CO}_{2}$ gas.

$$
\mathrm{CaCO}_{3}(\mathrm{~s}) \rightarrow \mathrm{CaO}(\mathrm{~s})+\mathrm{CO}_{2}(\mathrm{~g})
$$

For these types of reactions, the rate can be determined from a measurement of the volume of gas evolved during the reaction (you will practice such in a laboratory under this unit).

## Disruptive techniques: Chemical analysis method

In chemical analysis method, a required sample of the reaction mixture is taken out and analyzed, for example, titration to estimate the acid liberated during the hydrolysis of an ester. In the method of chemical analysis, to obtain the composition of the reaction mixture at a given time it is necessary to ensure that no further reaction takes place between sampling and analysis. This is usually achieved by lowering the temperature (quenching) of the mixture immediately after sampling.

### 1.5 Factors affecting the rate of a chemical reaction

Usually a balanced chemical equation is used to describe the quantitative relationships between the amounts of reactants present and the amounts of products that can be formed in a chemical reaction. As we have some idea from the previous sections, this balanced equation gives us no information about how fast a given reaction will occur. Such information is obtained by studying the chemical kinetics or rates of a reaction. The rate of the reaction depends on various factors: reactant concentrations, temperature, physical nature and surface areas of reactants, catalyst properties and solvent. By studying the kinetics of a reaction, it is possible to gain insights into how to control reaction conditions to achieve a desired outcome.

It is easy to get an idea that the rate of a chemical reaction can be increased by:
Increasing the concentration of a solution or raising the pressure (for a gas phase reaction), increasing the temperature of the reaction system, increasing the surface area of a solid

## G.C.E. (A/L) CHEMISTRY: UNIT 11 Chemical Kinetics

and by adding a catalyst. In addition to these, solvent used in an experiment to dissolve solute (reactant) can also affect the rate of reaction.

Insight into these can be understood by considering the basic requirements necessary to satisfy to occur a chemical reaction based on collision theory as discussed below.

### 1.6 Uses molecular kinetic theory (Collision Theory) to explain the effect of factors affecting the rate of chemical reactions

### 1.6.1 Collision theory

As we know from unit 4 (gaseous state of matter), collision theory explains the motion of molecules, their kinetic energy and how pressure changes in a system accordingly. Now it is easy to understand that for a reaction to occur the molecules must collide all the time and some fraction- but not all of those collisions will lead to transformation of the reactants to the products. This simply means that all the collisions will not result products. For example, at 1 atm and $20^{\circ} \mathrm{C}$, the $\mathrm{N}_{2}(\mathrm{~g})$ and $\mathrm{O}_{2}(\mathrm{~g})$ molecules in $1 \mathrm{~cm}^{3}$ of air experience about $10^{27}$ collisions per second. If all that was lead for a reaction atmosphere would consist of almost all NO; but only traces are present. This indicates that the number of collisions can't be the only factor which determines the occurrence of a reaction and a reaction rate. Therefore, following must be satisfied to occur a chemical reaction:

1. The molecules must come into contact leading to a collision.
2. They must collide with enough energy to overcome an energy barrier. This minimum energy required is called the activation energy for the reaction.
3. They must collide in favorable orientation that allows the necessary bondbreaking and forming needed to transform the reactants to the products.

## Collision:

According to kinetic molecular theory, the reactant molecules are considered to be hard spheres. The number of collisions per second per unit volume of the reaction mixture is known as collision frequency $(Z)$. In its basic form, collision theory deals with one-step reactions, those in which two particles collide and form products: $\mathrm{A}+\mathrm{B} \rightarrow$ products. Suppose we have only two particles of A and two of B confined in a vessel.

Figure 1.6 Increase in number of collisions with concentration of the reactants A and B in a constant volume of the reaction mixture. (a) Two molecules of A and two molecules of B can undergo four collisions. Likewise, in (b) when there are three molecules of A and 2 molecules are present total of six $(3 \times 2)$ collisions result. Three molecules of each A and B results nine $(3 \times 3)$ collisions as in $(\mathbf{c})$. Note that though the number of collision probabilities could predict like this, all the collisions may not result the product of the reaction.

Figure 1.6 shows that four A-B collisions are possible when there are two A and two B molecules. If we have three A and two B molecules, then there are six possible collisions and likewise when there are three A and three B molecules, we have nine possible collisions. Therefore, it can be noted that this probability of collision shows that the number of collisions depends on the product of the numbers of reactant particles, not their sum. Thus, collision theory explains that how the rate of a chemical reaction depends on the number of collisions per unit time per unit volume which in turn explains how the increase in concentration increases the reaction rate. Usually, this collision requirement has a large effect on what media are chosen to perform chemical reactions. Solids tend to be very slow reactors because only the atoms on the surface can have collisions with other atoms of other molecules. That's why the rusting of iron is very slow. Most reactions are done either in solution or in the gas phase where freedom of movement of the reactant molecules allows them to easily come into contact. Therefore, the more collisions per unit time per unit volume at a given temperature, the faster is the reaction rate.

## Collision orientation

It is easy to understand that in a situation involving two molecules they can only react together when they come into contact with each other. In this encounter, they first have to collide, and then they may react. This means that though the molecules collide with each other and all the collisions may not result the product. Reactant molecules must collide with a favorable orientation and they must have necessary activation energy to yield the desired product and such collisions are called effective collisions. The reaction rate increases with the increase in number of effective collisions and it is in turn proportional to the total number of collisions.

## Example:

Consider the single-step decomposition reaction of BrNO given below.

$$
2 \mathrm{BrNO}(\mathrm{~g}) \rightarrow 2 \mathrm{NO}(\mathrm{~g})+\mathrm{Br}_{2}(\mathrm{~g})
$$

Now let's see the way the two molecules of BrNO arrange in space as depicted in Figure 1.7. To form $\mathrm{Br}_{2}(\mathrm{~g})$ as a product, two Br atoms of the two molecules of BrNO should approach along the same line as shown in the first two collisions. However, if those molecules line up as depicted in third collision, there is no way to collide two Br atoms and hence the collision orientation would not produce the products in the reaction. Therefore, the proper line of approach or the direction of colliding reactant molecules control the rate of reaction.

(b)

$$
2 \mathrm{BrNO}(\mathrm{~g}) \longrightarrow 2 \mathrm{NO}(\mathrm{~g})+\mathrm{Br}_{2}(\mathrm{~g})
$$

Figure 1.7 Different orientations of collisions between two BrNO molecules. In (a) and (b), two molecules lined up properly and result the formation of a $\mathrm{Br}_{2}$ molecule and two NO molecules. In (c) though the molecules lined up, Br atoms are not in the favourable sides/directions to collide and to for in the products.

Consider another single-step reaction between ethene and HCl to produce chloroethane.

$$
\mathrm{CH}_{2}=\mathrm{CH}_{2}(\mathrm{~g})+\mathrm{HCl}(\mathrm{~g}) \rightarrow \mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{Cl}(\mathrm{~g})
$$

As a result of the collision between the two molecules, the $\mathrm{C}=\mathrm{C}$ double bond is converted into a single bond attaching hydrogen atom to one of the carbons and a chlorine atom to the other. The desired product of the reaction is only possible if the hydrogen end of the $\mathrm{H}-\mathrm{Cl}$ bond approaches the carbon-carbon double bond. $\mathrm{C}=\mathrm{C}$ has a high electron density around it and if the Cl atom approaches it, the Cl atom is repelled leading to no products. The collisions leads to the products and the other possible collisions the collisions which do not lead to products are compared in Figure 1.8.

\mathrm{CH}_{2}=\mathrm{CH}_{2}(\mathrm{~g})+\mathrm{HCl}(\mathrm{~g}) \rightarrow \mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{Cl}(\mathrm{~g})
$$

Figure 1.8 Possible orientations of collisions between $\mathrm{CH}_{2}=\mathrm{CH}_{2}$ and HCl molecules. In (a) hydrogen atom of HCl oriented towards the $\mathrm{C}=\mathrm{C}$ bond and as the $\mathrm{C}=\mathrm{C}$ bond has negative charge, this collision favours the product. In (b), Cl atom of HCl is repelled thus the reaction is not favoured. In (c) and (d) product is not favoured.

## Surmounting the activation energy barrier

We know that a sample of reactant molecules in motion will have a Boltzmann distribution of molecular kinetic energies. Some molecules will have high energy; some low; many with intermediate energies. Figure 1.9 shows Boltzmann plots for a set of reactants at two different temperatures. Only those reactant molecules with energies greater than a certain minimum (threshold) energy called the activation energy, $\boldsymbol{E}_{a}$ (to the right of the plot) will be able to yield products. Because a greater fraction of molecules in the high temperature sample exceed the activation energy, the high-temperature sample will have more effective collisions and will experience a faster reaction rate compared to the sample at low temperature.

Figure 1.9 The effect of temperature on the distribution of collision energies. At higher temperature fraction of molecules having energy more than the activation energy increases leading to higher reaction rates.

When a favorable collision occurs between molecules overcoming the forces of interactions among the molecules, first an unstable molecule cluster, called the activated complex (transition state) is formed. The life time of the activated complex is very short and transformed to the products (or may break into the reactants again). The activation energy ( $E_{a}$ ) depends upon the nature of chemical bonds undergoing rupture and is independent of enthalpies of reaction. The energy diagram for this with the example of the decomposition of $\operatorname{BrNO}(\mathrm{g})$ is shown in Figure 1.10 More details on this will be discussed later.

Figure 1.10 Energy diagram in which the activation energy $\left(\mathrm{E}_{\mathrm{a}}\right)$ is depicted
For example, in the decomposition reaction $2 \mathrm{BrNO}(\mathrm{g}) \rightarrow 2 \mathrm{NO}(\mathrm{g})+\mathrm{Br}_{2}(\mathrm{~g})$, of $\mathrm{BrNO}(\mathrm{g})$ two $\mathrm{Br}-\mathrm{N}$ bonds need to be broken and one $\mathrm{Br}-\mathrm{Br}$ bond needs to be formed. The energy required to break a $\mathrm{Br}-\mathrm{N}$ bond is about $243 \mathrm{~kJ} \mathrm{~mol}^{-1}$ and hence this energy must be required to occur the reaction. Based upon the collision model, the energy comes from the kinetic energy of the molecules and once the molecules collide, the kinetic energy is transferred into potential energy which breaks the bonds and rearranges the atoms.

As a summary we can see that a chemical reaction whether exothermic or endothermic has an energy barrier which has to be overcome before reactants can be transformed into products. If the reactant molecules have sufficient energy, they can reach the peak of the energy barrier after an effective collision and then they can go to the right side of the curve and consequently change into products. If the activation energy for a reaction is low, the fraction of effective/ favourable collisions will be large and the reaction will be fast. On the other hand, if the activation energy is high, then fraction of effective collisions will be small and the reaction will be slow. When temperature is increased, the number of collisions and the number of effective collisions per unit time per unit volume will increase and hence the rate of reaction will increase.

## Concentration effects

In a chemical reaction of the type $\mathrm{A}+\mathrm{B} \rightarrow$ Products: reactant molecules of A and B (atoms, or ions) come into contact and converted into products. If there is no contact, the reaction rate will be zero. If the number of molecules per unit volume is increased the reaction rate increases as the collisions between them increase. This means that the reaction rate usually increases as the concentration of the reactants increases. In reactions involving liquids or gases, increasing the concentration of the reactants increases the rate of reaction. In a few cases, increasing the concentration of one of the reactants may not have an effect of the rate (Details of this is discussed in a latter section). The reaction between solid $\mathrm{CaCO}_{3}$ and HCl acid can be used to demonstrate this concentration effect:

$$
\mathrm{CaCO}_{3}(\mathrm{~s})+2 \mathrm{HCl}(\mathrm{aq}) \rightarrow \mathrm{CaCl}_{2}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})+\mathrm{CO}_{2}(\mathrm{~g})
$$

The rate of reaction can be altered by changing the concentration of the acid. (Also size of the calcium carbonate chips can be changed and it comes under the physical nature of the reactant). In this reaction it has been observed that if the $\mathrm{CaCO}_{3}$ chips are large and in excess, then only a small fraction of the solid reacts. The rate will decrease over time as the hydrochloric acid is consumed because the concentration of HCl decreases over the time. Therefore, the rate of reaction can be monitored by measuring the pH of the solution, the decrease in the mass of calcium carbonate, or the increase in the volume of carbon dioxide. The easiest way is the volume measurement of the evolved $\mathrm{CO}_{2}$ as it is the only gaseous species formed. In a particular experiment if we allow to react a known amount of $\mathrm{CaCO}_{3}$ separately with a known volume of $\left(\sim 100 \mathrm{~cm}^{3}\right)$ of $0.50,1.00$ and 2.00 mol $\mathrm{dm}^{-3} \mathrm{HCl}$ solutions, and monitor the volume of $\mathrm{CO}_{2}$ formed with the time, following results could be observed (Figure 1.11).

Figure 1.11 The variation in time for the generation of a constant volume of $\mathrm{CO}_{2}(\mathrm{~g})$ with the concentration of HCl in a reaction $\mathrm{CaCO}_{3}(\mathrm{~s})+2 \mathrm{HCl}(\mathrm{aq}) \rightarrow \mathrm{CaCl}_{2}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})+\mathrm{CO}_{2}(\mathrm{~g})$ at a given temperature.

From the above graph it can be seen that the time taken to produce a constant volume of $\mathrm{CO}_{2}$ gas decreases $\left(\mathrm{t}_{2.00}<\mathrm{t}_{1.00}<\mathrm{t}_{0.50}\right)$ with the increasing concentration of HCl . That
is the rate of the reaction increases with the increasing concentration of HCl . The reason for this increased rate is explained by the collision theory. At high concentrations collisions per unit time per unit surface area of $\left(\mathrm{CaCO}_{3}\right)$ among reactants increase and hence the rate of the reaction.

Though the reaction rate increases with concentration, it has to be noted that in certain type of reactions (multi-step) this phenomenon does not exist. For example, consider a reaction which occurs in a series of steps having widely different rates where some of the steps are fast and some of them are slow.

Suppose two reactants $A$ and $B$ react together to give product $P$ in the following two steps:

$$
\begin{array}{cc}
\mathrm{A}(\mathrm{aq}) \rightarrow \mathrm{X}(\mathrm{aq}) & : \text { slow } \\
\mathrm{B}(\mathrm{aq})+\mathrm{X}(\mathrm{aq}) \rightarrow & \mathrm{P}: \text { fast }
\end{array}
$$

In the above reaction overall rate of the reaction is controlled by the slow step in which A makes X. This is described as the rate determining step of the reaction.

If the concentration of A is increased, it is clear that the rate of that step increases as described above. However, if the concentration of B is increased, of course, the rate of the step increases but that does not make any impact on the overall rate of the reaction because that the step happens very fast as soon as any X is formed. Therefore, in such a multi-step reaction, increase in the concentration of a particular reactant which involves in the fast step does not show any impact on the reaction rate. Nucleophilic substitution reactions are some of the examples for this type of reactions.

## Pressure effects

Increasing the pressure of a reaction involving gaseous reactants increases the rate of reaction. Changing the pressure of a reaction involving only solids or liquids has no effect on the rate. For example, in the manufacture of ammonia by the Haber process, the rate of reaction is increased by the use of very high pressures. Increasing the pressure of a gas is exactly the same as increasing its concentration for a given mass of gas as can be understood from the ideal gas equation as follows.

$$
P V=n R T
$$

For a given mass of gas, we can rearrange the above equation as;
$P=\frac{n}{V} R T=C R T$ for a given volume at a constant temperature. As a product $(R T)$ is a constant at constant temperature, pressure is directly proportional to the concentration. It is clear that when the pressure is increased collision between two different particles or two of the same particles increases and hence the rate of reaction. This is true for the systems with the both reacting molecules are in gaseous state at constant volume, or whether one is a gas and the other is a solid as described in the Figure 1.11.

Figure 1.12 Effect of the pressure: Increase in pressure increases the concentrations of gaseous reactants.

## Temperature effects

It has been understood that changing the temperature affects the rate of a reaction. As described in the above with the Maxwell-Boltzmann distribution of molecular energies in a gas increase in the temperature leads the rate of reaction to increase. For many reactions (not for all reactions) happening at around the room temperature, the rate of reaction approximately doubles for every $10^{\circ} \mathrm{C}$ rise in temperature. Some reactions are virtually instantaneous (very fast). Examples are precipitation reactions from participant ions in solution to make an insoluble solid, or the reaction between hydrogen ions from an acid and hydroxide ions from an alkali in solution. So heating one of these would not make any acceptable or significant difference in the rate of the reaction.

As described in Unit 4 (gaseous state of matter) the increase in temperature of a system increases the average kinetic energy of its constituent molecules/particles. As the average kinetic energy increases, the particles move faster and collide more frequently per unit time (per unit volume). This leads to increase the fraction of molecules processing energy for productive collisions (or in other words, exceeds the activation energy of the reaction). Both of these factors increase the reaction rate. Hence, the reaction rate of all (most) reactions increases with increasing temperature. Details of this will be discussed in a latter section. Conversely, the rate of reactions decreases with decreasing temperature. For example, refrigeration slows down the growth of bacteria in foods by decreasing the reaction rates of biochemical reactions that enable bacteria to reproduce.

In addition, in the systems where more than one reaction is possible, the same reactants can produce different products under different reaction conditions. For example, in the

## G.C.E. (A/L) CHEMISTRY: UNIT 11 Chemical Kinetics

presence of dilute sulfuric acid and at temperatures around $100^{\circ} \mathrm{C}$, ethanol is converted to diethyl ether:

$$
2 \mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}(\mathrm{aq}) \xrightarrow{\mathrm{H}_{2} \mathrm{SO}_{4}} \mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OCH}_{2} \mathrm{CH}_{3}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

At $180^{\circ} \mathrm{C}$, however, a completely different reaction occurs, which produces ethylene as the major product:

$$
\mathrm{CH}_{3} \mathrm{CH}_{2} \mathrm{OH}(\mathrm{aq}) \xrightarrow{\mathrm{H}_{2} \mathrm{SO}_{4}} \mathrm{C}_{2} \mathrm{H}_{4}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{O}(l)
$$

## Physical nature of the reactants

Consider a reaction of two reactant molecules in the same liquid phase. They collide more frequently than when one or both reactants are solids (or when they are in different immiscible liquid phases). If the reactant molecules are uniformly dispersed in a single homogeneous solution, then the number of collisions per unit time per unit volume depends on concentration and temperature. If the reaction is heterogeneous, the reactants are in two different phases (solid/gas), and collisions between the reactants can occur only at the interface between the two phases. The number of collisions between reactants per unit time per unit volume is substantially reduced relative to the homogeneous case, and, hence, so is the reaction rate. Usually rates of reactions depend on the physical state as Gaseous state > Liquid state > Solid state. The reaction rate of a heterogeneous reaction depends on the surface area of the more condensed phase.

In automobile engines, surface area effect on the reaction rate is used. Gasoline is injected into each cylinder, where it combusts on ignition by a spark from the spark plug. The gasoline is injected in the form of microscopic droplets because in that form it has a much larger surface area and can burn much more rapidly than if it were fed into the cylinder as a stream. Similarly, a pile of finely divided iron burns slowly (or not at all), but spraying finely divided dust into a flame produces a vigorous reaction.

In the case of solid reactant, a more finely powdered solid reacts faster than the same mass present as a single lump because the powdered solid has a greater surface area than the single lump.

For example in the calcium carbonate and hydrochloric acid reaction in the laboratory you can observe that the powdered calcium carbonate reacts much faster with dilute hydrochloric acid than if the same mass was present as lumps of marble or limestone.

In the catalytic decomposition of hydrogen peroxide solid manganese(IV) oxide is often used as the catalyst. Oxygen is given off much faster if the catalyst is present as a powder than as the same mass of granules.

For example, in a reaction between magnesium metal and a dilute hydrochloric acid involves collision between magnesium atoms and hydrogen ions. The surface area of the
metal here also affects the rate of the reaction. Fine magnesium powder causes evolution of hydrogen gas more rapidly than the magnesium strip.

Not only the physical nature as described earlier but nature of chemical bonds in reactants affects the rate.

Consider the following two reactions:

$$
\begin{align*}
& 2 \mathrm{NO}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \rightarrow 2 \mathrm{NO}_{2}(\mathrm{~g})  \tag{a}\\
& \mathrm{CH}_{4}(\mathrm{~g})+2 \mathrm{O}_{2}(\mathrm{~g}) \rightarrow \mathrm{CO}_{2}(\mathrm{~g})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{~g}) \tag{b}
\end{align*}
$$

The first reaction (a) is faster than the second because in the first reaction only $\mathrm{N}=\mathrm{O}$ bond is to be broken where as in the second reaction (b) four C-H bonds are to be broken.

Similarly consider another example of two similar reactions:

$$
\begin{align*}
& 2 \mathrm{NO}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \rightarrow 2 \mathrm{NO}_{2}(\mathrm{~g})  \tag{c}\\
& 2 \mathrm{CO}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \rightarrow 2 \mathrm{CO}_{2}(\mathrm{~g}) \tag{d}
\end{align*}
$$

NO bond is weaker than CO bond, hence is broken easily. Thus reaction (c) is faster than (d).

## Solvent effects

The nature of the solvent can also affect the reaction rates. The same reaction occurring in different solvents shows different rates depending on the polarities of solvents used.

When the reaction occurs in the same solvent, viscosity is also important in determining reaction rates. In highly viscous solvents, dissolved particles diffuse much more slowly than in less viscous solvents and can collide less frequently per unit time per unit volume. Thus the reaction rates decrease with increasing solvent viscosity.

## Catalyst effects

A catalyst is a substance that participates in a chemical reaction and increases the reaction rate by changing the path of the reaction without undergoing a net chemical change itself. For example, the reaction $\mathrm{CO}(\mathrm{g})+2 \mathrm{H}_{2}(\mathrm{~g}) \rightarrow \mathrm{CH}_{3} \mathrm{OH}(\mathrm{g})$ is very slow at room temperature and can be speeded up by introducing a catalyst. In addition, the decomposition of hydrogen peroxide in the presence of catalyst occurs in much more rapidly compared to the rate of that reaction without a catalyst. Because most catalysts are specific to certain reactions, they often determine the product of a reaction by accelerating only one of several possible reactions that could occur. In particular reactions with a catalyst the increase in concentration of the reactants sometimes may not increase the rate of reaction. For example, when a small amount of finely powdered solid catalyst is used in a reaction with a high enough concentration of reactant in solution the catalyst surface is totally covered up with reacting particles. Increasing the concentration of the solution even more
cannot make any effect because the catalyst is already working at its maximum capacity. Details of these effects on the reaction rate and mechanisms will be discussed in a separate section.

### 1.7 Controlling the rate of a reaction by appropriately manipulating the concentration of reactants

### 1.7.1 Expressing the rate of a reaction: Average, instantaneous and initial rates

As described earlier the rate varies as a reaction proceeds. Consider the following hypothetical gas phase reaction between $\mathbf{A}$ and $\mathbf{B}$.

$$
\mathrm{A}(\mathrm{~g})+\mathrm{B}(\mathrm{~g}) \rightarrow \mathrm{C}(\mathrm{~g})
$$

For every molecule of $\mathbf{A}$, a molecule of $\mathbf{B}$ reacts and hence $[\mathbf{A}]$ and $[\mathbf{B}]$ decrease at the same rate and we can write:

$$
\text { Rate }=-\frac{\Delta[\mathrm{A}]}{\Delta t}=-\frac{\Delta[\mathrm{B}]}{\Delta t}
$$

Assume that the reaction is started with a known [A] in a closed vessel at 298 K and the concentration of is manured A at 10 second intervals after adding B . The obtained data can be plotted as shown in Figure 1.13. Rate decreases during the progress of the reaction because the reactant concentration decreases with the time (As A molecules react, the number of effective collisions decreases and hence the rate). If we plot the concentration of the products with the time the opposite curve will result. With the help of the plot of concentration vs time, following three types of rates can be defined.

Figure 1.13 Definitions and graphical expression of reaction rates; average, instantaneous and initial rates: (a); change in rate for the reactants and (b); change in rate for the products. Note that the quantity of rate takes negative sign (as the slope is negative) and that for the products is positive. Therefore, in the calculations rate of consumption of reactants is multiplied by $(-1)$.

## G.C.E. (A/L) CHEMISTRY: UNIT 11 Chemical Kinetics

## Average rate

Over a given period of time, the average rate is the slope of the line joining two points along the curve. The average rate over the first 100 s time interval is the change in concentration during that time interval divided by the time taken. For example, when $\mathrm{C}_{1}=3.50 \times 10^{-5}$ and $\mathrm{C}_{2}=0.50 \times 10^{-5} \mathrm{~mol} \mathrm{dm}^{-3}$,

$$
\begin{aligned}
\operatorname{Rate}_{0-100}=- & \frac{\Delta[A]}{\Delta t}=-\frac{\left[0.50 \times 10^{-5}-3.50 \times 10^{-5}\right] \mathrm{mol} \mathrm{dm}^{-3}}{[100-0] \mathrm{s}} \\
& =3.0 \times 10^{-7} \mathrm{~mol} \mathrm{dm}
\end{aligned}
$$

This shows that during the first 100 s of the reaction, [A] decreases with the average of $3.0 \times 10^{-7} \mathrm{~mol} \mathrm{dm}^{-3}$ each second. However, this does not imply that the rate at any point along the curve is $3.0 \times 10^{-7} \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{~s}^{-1}$. We can clearly understand that the slope of the curve decreases with the time and hence the rate (average) should also decrease.

That means the rate over shorter intervals may be lower or higher than the average. In the above estimation in whole 100 s interval the decrease in [A] does not show the rate over any shorter time period. This change in reaction rate is evident when we calculate the average rate over two shorter periods. For example, in the first 10 s the average rate is given by ( $\mathrm{C}_{1}=3.50 \times 10^{-5}$ and $\mathrm{C}_{2}=3.00 \times 10^{-5} \mathrm{~mol} \mathrm{dm}^{-3}$ );

$$
\begin{aligned}
\operatorname{Rate}_{0-10}=- & \frac{\Delta[A]}{\Delta t}=-\frac{\left[3.00 \times 10^{-5}-3.50 \times 10^{-5}\right] \mathrm{mol} \mathrm{dm}^{-3}}{[10-0] s} \\
& =5.0 \times 10^{-7} \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{~s}^{-1}
\end{aligned}
$$

Likewise the average rate in the $50-60 \mathrm{~s}$ interval is when $\mathrm{C}_{1}=1.00 \times 10^{-5}$ and $\mathrm{C}_{2}=0.75 \times 10^{-5} \mathrm{~mol} \mathrm{dm}^{-3}$.

$$
\begin{aligned}
\text { Rate }_{50-60}=- & \frac{\Delta[A]}{\Delta t}=-\frac{\left[0.75 \times 10^{-5}-1.00 \times 10^{-5}\right] \mathrm{mol} \mathrm{dm}^{-3}}{[60-50] \mathrm{s}} \\
& =2.50 \times 10^{-7} \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{~s}^{-1}
\end{aligned}
$$

## Instantaneous rate

Average rate which is a constant for the time interval interested cannot be used to predict the rate of a reaction at a particular instant. So, to express the rate at a particular instant of time the instantaneous rate is determined. Rate of the reaction at a certain time is called as an instantaneous rate. The slope of a line tangent to the curve at any point gives the instantaneous rate at that time.

For example, the instantaneous rate at 50.0 s is;
To calculate this it is necessary to calculate the slope of the tangent line drawn to the curve at 50.0 s . Related points considered are $\left(65,1.25 \times 10^{-5}\right)$ and $\left(35,0.75 \times 10^{-5}\right)$

$$
\text { Rate }_{50}=-\frac{\Delta[\mathrm{A}]}{\Delta t}=-\frac{\left[(0.75-1.25) \times 10^{-5}\right] \mathrm{mol} \mathrm{dm}^{-3}}{[65-35] \mathrm{s}}=1.70 \times 10^{-7} \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{~s}^{-1}
$$

It is very clear that the instantaneous rate is different from the average rate and in general, we use the term reaction rate to mean instantaneous reaction rate.

## Initial rate

The instantaneous rate at the moment the reactants are mixed (that is, at $t=0$ ) is the initial rate. Initial rate is calculated from the slope of the line tangent to the curve at $t=0 \mathrm{~s}$ (Figure 1.13). Measurements of initial rates is usually used in chemical kinetics to find other kinetic parameters.

When there is a reversible reaction the use of initial rate poses some complications. As a reaction proceeds in the forward direction (products $\rightarrow$ reactants), product increases, causing the reverse reaction (products $\rightarrow$ reactants), to occur more quickly. To find the overall (net) rate, we would have to calculate the difference between the forward and reverse rates. But, for the initial rate, $t=0$, so product concentrations are negligible. So the rate of the reverse reaction would not affect the estimations.

As such in the simple way the initial rate or the instantaneous rate at $t=0$, occurs when reactants have just been mixed and before any product accumulates.

### 1.7.2 Effect of concentration on reaction rate

## Rate law

From the above section it is known that the frequency of effective collisions controls reaction rates. The more effective collisions mean the faster the rate. There are two ways to increase the frequency of collisions between molecules: increase the number of molecules in a constant volume at a given temperature or increase the kinetic energy of them by raising temperature. Increasing the number of molecules in a constant volume means the increase in concentration.

As was explained previously, for many reactions involving liquids or gases, increasing the concentration of the reactants increases the rate of reaction due to the increase in collision frequency. In some cases, increasing the concentration of one of the reactants may not affect the rate and also doubling the concentration of one of the reactants may not double the rate of the reactions always. Therefore, it is necessary to understand the behavior of concentration dependence of the reaction rate quantitatively with some models.

Consider a simple reaction;

$$
\mathrm{A} \rightarrow \mathrm{~B}
$$

We can write,

$$
\begin{gathered}
\quad \text { Rate } \alpha[\mathrm{A}] \\
\therefore \text { Rate }=\mathrm{k}[\mathrm{~A}]
\end{gathered}
$$

where $\boldsymbol{k}$ is the proportionality constant and is called the "rate constant". The above expression is called the rate law expression or rate law of the reaction $\mathrm{A} \rightarrow \mathrm{B}$. In this reaction we can say that the rate of the reaction is proportional to the concentration of A . If we assure that doubling the concentration of A doubles the rate and we can then write the rate law as;

$$
\text { Rate }=\mathrm{k}[\mathrm{~A}]^{1}=\mathrm{k}[\mathrm{~A}]
$$

Consider the following decomposition reaction.

$$
\mathrm{NH}_{4} \mathrm{NCO}(\mathrm{aq}) \rightarrow\left(\mathrm{NH}_{2}\right)_{2} \mathrm{CO}(\mathrm{aq})
$$

It has been experimentally found that the rate of the above reaction is proportional to the above square of the $\mathrm{NH}_{4} \mathrm{NCO}(\mathrm{aq})$ concentration. That is when the concentration of $\mathrm{NH}_{4} \mathrm{NCO}(\mathrm{aq})$ is doubled the rate will quadruple. Therefore, the rate law for the reaction can be written as,

$$
\text { Rate }=k\left[\mathrm{NH}_{4} \mathrm{NCO}_{(\mathrm{aq})}\right]^{2}
$$

From the above it can be noted that there are three parts appear in the rate law;
$\boldsymbol{k}$ : rate constant; For a given reaction it has a number and (appropriate) units. Rate constant is different for different reactions and is different for the same reaction at different temperatures.
[ $\mathrm{NH}_{4} \mathrm{NCO}(\mathrm{aq})$ ]: the concentration of the reactants; If more than one reactant is present, any or all of them may be present in the equation. Sometimes it is the case that one or more reactants will not be appearing in the rate law.

2: the order of the reaction with respect to the relevant reactant; This is more often an integer like 1,2 . but fractions are also possible sometimes. If the order is one, 1 is not written in the rate law expression. The order of the reaction can also be more than 2 . However, they are not included in this discussion.

Experimentally derived rate laws for two reactions are given below.

$$
\begin{array}{ll}
2 \mathrm{NO}_{(\mathrm{g})}+\mathrm{O}_{2}(\mathrm{~g}) \rightarrow \mathrm{NO}_{2}(\mathrm{~g}): & \text { Rate }=k[\mathrm{NO}(\mathrm{~g})]^{2}\left[\mathrm{O}_{2}(\mathrm{~g})\right] \\
\mathrm{NO}_{2}(\mathrm{~g})+\mathrm{CO}(\mathrm{~g}) \rightarrow \mathrm{NO}_{(\mathrm{g})}+\mathrm{CO}_{2}(\mathrm{~g}): & \text { Rate }=k\left[\mathrm{NO}_{2}(\mathrm{~g})\right]^{2}
\end{array}
$$

Now consider a general reaction between reactants A and B;

$$
\mathrm{aA}+\mathrm{bB} \rightarrow \text { Products }
$$

## G.C.E. (A/L) CHEMISTRY: UNIT 11 Chemical Kinetics

The rate law for the reaction can be written as,

$$
\text { Rate }=\boldsymbol{k}[\mathrm{A}]^{x}[\mathrm{~B}]^{y}
$$

From the above examples concentrations of $\mathbf{A}$ and $\mathbf{B}$ have to be raised to some power $\boldsymbol{x}$ and $\mathbf{y}$ to show how they affect the rate of the reaction. These powers are called the orders of the reaction with respect to $\mathbf{A}$ and $\mathbf{B}$. The sum of $x$ and $y,(\boldsymbol{x}+\mathbf{y})$ is called as the overall order of the reaction.
i.e the sum of powers of the concentration terms of the reactants written in the rate law expression is called the overall order of that chemical reaction.

If the order of reaction with respect to $\mathbf{A}$ is 0 (zero), this means that the concentration of A doesn't affect the rate of the reaction. Mathematically, any number raised to the power zero is equal to 1 . That is why that particular concentration term disappears from the rate equation.

Therefore, rate law is the expression in which reaction rate is given in terms of molar concentration of reactants with each term raised to some power, which may or may not be same as the stoichiometric coefficient of the reacting species in a balanced chemical equation.

Let's consider some examples of observed rate laws and note the reaction orders. For the reaction between NO and $\mathrm{H}_{2}$ gases,

$$
2 \mathrm{NO}(g)+2 \mathrm{H}_{2}(g) \rightarrow \mathrm{N}_{2}(g)+2 \mathrm{H}_{2} \mathrm{O}(g)
$$

the rate law is

$$
\text { Rate }=k[\mathrm{NO}(\mathrm{~g})]^{2}\left[\mathrm{H}_{2}(\mathrm{~g})\right]
$$

This reaction is second order with respect to NO. And, even though $\mathrm{H}_{2}(\mathrm{~g})$ has the stoichiometric coefficient of 2 in the balanced equation, the reaction is first order with respect to $\mathrm{H}_{2}(\mathrm{~g})$. It is third order overall.

For the reaction between nitrogen monoxide and ozone,

$$
\mathrm{NO}(g)+\mathrm{O}_{3}(g) \rightarrow \mathrm{NO}_{2}(g)+\mathrm{O}_{2}(g)
$$

the rate law is

$$
\text { Rate }=k[\mathrm{NO}(\mathrm{~g})]\left[\mathrm{O}_{3}(\mathrm{~g})\right]
$$

This reaction is first order with respect to $\mathrm{NO}(\mathrm{g})$ and first order with respect to $\mathrm{O}_{3}(\mathrm{~g})$, thus it is second order overall.

For the hydrolysis of 2-bromo-2-methylpropane,

$$
\left(\mathrm{CH}_{3}\right)_{3} \mathrm{CBr}(\mathrm{l})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightarrow\left(\mathrm{CH}_{3}\right)_{3} \mathrm{COH}(\mathrm{l})+\mathrm{HBr}(\mathrm{aq})
$$

the rate law is

$$
\text { Rate }=k\left[\left(\mathrm{CH}_{3}\right)_{3} \mathrm{CBr}(\mathrm{l})\right]
$$

This reaction is first order with respect to 2-bromo-2-methylpropane and zero order with respect to $\mathrm{H}_{2} \mathrm{O}(l)$, despite its coefficient of 1 in the balanced equation. If we want to note that water is a reactant, we can write the rate law as follows.

$$
\text { Rate }=k\left[\left(\mathrm{CH}_{3}\right)_{3} \mathrm{CBr}(\mathrm{l})\right]\left[\mathrm{H}_{2} \mathrm{O}(\mathrm{l})\right]^{0}
$$

This is a first order reaction overall.

The above examples give an important point:
Rate law for any reaction cannot be predicted by merely looking at the balanced chemical equation and must be determined experimentally. Although the rate constant is really a number with appropriate units, when describing a general rate law, we usually just write $\boldsymbol{k}$ but any value is true only at one temperature.

The rate of a reaction is always expressed in terms of mol dm ${ }^{-3} \mathrm{~s}^{-1}$. We can classify the reactions as zeroth, first, second, etc. order reactions. Assuming time is measured in seconds, The corresponding units of the rate constant can be derived as follows.

## Zero order reactions

Consider the reaction; A $\rightarrow$ products

If the reaction is zero order, the rate law is,

$$
\text { Rate }=k
$$

The units of k must be the same as that of rate, $\mathbf{m o l ~ d m}^{-\mathbf{3}} \mathbf{s}^{\mathbf{- 1}}$.

## First order reactions

Consider the reaction; A $\rightarrow$ products

If the reaction is first order, the rate law is,
Rate $=k$ [A]
Units of $k ;=\frac{\text { Rate }}{[\mathrm{A}]}=\frac{\mathrm{mol} \mathrm{dm}^{-3} \mathrm{~s}^{-1}}{\mathrm{~mol} \mathrm{dm}^{-3}}=\mathbf{s}^{\mathbf{- 1}}$.

## Second order reactions

Consider a reactions $\mathrm{A} \rightarrow$ products or $\mathrm{A}+\mathrm{B} \rightarrow$ products
If the reaction is second order, the rate law is,
Rate $=k[\mathrm{~A}]^{2}$ or Rate $=k[\mathrm{~A}][\mathrm{B}]$
Units of $k$; $=\frac{\text { Rate }}{[\mathrm{A}]^{2}}=\frac{\mathrm{mol} \mathrm{dm}^{-3} \mathrm{~s}^{-1}}{\mathrm{~mol}^{2} \mathrm{dm}^{-6}}=\mathbf{m o l}^{\mathbf{- 1}} \mathbf{d m}^{\mathbf{3}} \mathbf{s}^{\mathbf{- 1}}$.

## Example 1.8

Methyl acetate reacts with hydroxide ion according to the following equation.

$$
\mathrm{CH}_{3} \mathrm{COOCH}_{3}(\mathrm{aq})+\mathrm{OH}^{-}(\mathrm{aq}) \rightarrow \mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})+\mathrm{CH}_{3} \mathrm{OH}(\mathrm{aq})
$$

The rate law is;

$$
\text { Rate }=\mathrm{k}\left[\mathrm{CH}_{3} \mathrm{COOCH}_{3}(\mathrm{aq})\right][\mathrm{OH}-(\mathrm{aq})]
$$

What is the order of reaction with respect to each reactant, and the overall reaction order?

## Answer

Because there are no superscripts to the right of each concentration term in the rate law, it means they are each first order. The reaction is first order in $\mathrm{CH}_{3} \mathrm{COOCH}_{3}(\mathrm{aq})$ and first order in $\mathrm{OH}^{-}(\mathrm{aq})$. It is second order overall $(1+1=2)$.

For example let's consider experimentally derived rate laws for the following reactions;

$$
2 \mathrm{NO}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \rightarrow \mathrm{NO}_{2}(\mathrm{~g}): \quad \text { Rate }=k[\mathrm{NO}(\mathrm{~g})]^{2}\left[\mathrm{O}_{2}(\mathrm{~g})\right]
$$

The reaction is second order with respect to $\mathrm{NO}(\mathrm{g})$ and first order with respect to $\mathrm{O}_{2}(\mathrm{~g})$. Overall order of the reaction is 3.
$\mathrm{NO}_{2}(\mathrm{~g})+\mathrm{CO}(\mathrm{g}) \rightarrow \mathrm{NO}(\mathrm{g})+\mathrm{CO}_{2}(\mathrm{~g}): \quad$ Rate $=k\left[\mathrm{NO}_{2}(\mathrm{~g})\right]^{2}$
The reaction is second order with respect to $\mathrm{NO}_{2}(\mathrm{~g})$ and zero order with respect to $\mathrm{CO}(\mathrm{g})$. Overall order of the reaction is 2 .

## Example 1.9

Identify the reaction order from each of the following rate constants.

## Answer

(i) $k=5.6 \times 10^{-5} \mathrm{dm}^{3} \mathrm{~mol}^{-1} \mathrm{~s}^{-1}$

The unit of second order rate constant is $\mathrm{dm}^{3} \mathrm{~mol}^{-1} \mathrm{~s}^{-1}$
$\therefore k=5.6 \times 10^{-5} \mathrm{dm}^{3} \mathrm{~mol}^{-1} \mathrm{~s}^{-1}$ represents the second order reaction.
(ii) $k=3 \times 10^{-4} \mathrm{~s}^{-1}$.

The unit of a first order rate constant is $s^{-1}$
$\therefore k=3 \times 10^{-4} \mathrm{~s}^{-1}$ represents the first order reaction.

Table 1.1 summarizes the difference in rate of a reaction and rate constant to avoid the confusion between them.

Table 1.1 The difference in rate of a reaction and rate constant

| Rate of reaction | Rate constant |
| :--- | :--- |
| It is the speed of conversion of reactants <br> into products. | It is a proportionality constant. |
| It is measured as the rate of decrease of  <br> concentration of reactants or the rate of It is equal to the rate of reaction when <br> the concentration of each of the  |  |
| increase of concentration of products with <br> time. | reactants is unity. |
| It depends upon the initial concentration of <br> reactants. | It is independent of the initial <br> concentration of the reactants. It has a <br> constant value for a given reaction at a <br> fixed temperature. |

### 1.7.3 Graphical representation of change in rate with concentration for zero, first and second order reactions

## Zero order reactions

Zero order reactions means that the rate of the reaction is independent of the concentration of the reactants or we can say that the rate is proportional to zeroth power of the concentration of reactants. Consider the reaction,

$$
\begin{gathered}
\mathrm{A} \rightarrow \text { Products } \\
\text { Rate }=\mathrm{k}[\mathrm{~A}]^{0}=\mathrm{k}
\end{gathered}
$$

Therefore, for any given concentration of A, the rate does not change implying that the rate is a constant with the concentration. Hence the plot of rate against the concentration is a horizontal straight line as shown in Figure 1.14 (a). In other words, the change in concentration over the time is a constant which can be obtained from the slope of the graph of concentration over the time as shown in Figure 1.14(b).

Figure 1.14 (a) Variation of reaction rate over the concentration of the reactant and
(b) Variation of concentration of the reactant over the time for a zeroorder reaction.

## G.C.E. (A/L) CHEMISTRY: UNIT 11 Chemical Kinetics

The behaviour of the zero order reaction can be treated as follows too.
Consider a reaction:

$$
\mathrm{A}+\mathrm{B} \rightarrow \text { Products }
$$

Rate of the reaction is,

$$
\text { Rate }=k[\mathrm{~A}]^{\mathrm{a}}[\mathrm{~B}]^{\mathrm{b}}
$$

Assume that the concentration of B is very high and change in its concentration is negligible during the course of reaction. Therefore, the rate of reaction can be written as,

$$
\text { Rate }=k^{\prime}[\mathrm{A}]^{\mathrm{a}} \quad \text { where } k^{\prime}=k[\mathrm{~B}]^{\mathrm{b}}
$$

As the reaction is zero order with respect to A, Rate $=k^{\prime}=$ constant

Therefore, the graph of rate verses the concentration is again a horizontal straight line as described above.

Some photochemical reactions and a few heterogeneous reactions are examples for zeroorder reactions. Such reactions are not common.

## Photochemical reaction between hydrogen and chlorine:

$$
\mathrm{H}_{2}(\mathrm{~g})+\mathrm{Cl}_{2}(\mathrm{~g}) \xrightarrow{\mathrm{h} v} 2 \mathrm{HCl}(\mathrm{~g})
$$

This photochemical reaction is a zero-order reaction. The reaction is studied by placing $\mathrm{H}_{2}$ and $\mathrm{Cl}_{2}$ gases over water. The rate of reaction is studied by noting the rate at which water rises in the vessel due to dissolving of HCl formed. The rate of rise of water is the same as the rate of disappearance of $\mathrm{H}_{2}$ and $\mathrm{Cl}_{2}$, i.e., the concentration of the gaseous phase will not change with time, although the quantities will change.

Decomposition of $\mathrm{N}_{2} \mathrm{O}(\mathrm{g})$ on a hot platinum surface:

$$
\begin{aligned}
& \mathrm{N}_{2} \mathrm{O}(\mathrm{~g}) \rightarrow \mathrm{N}_{2}(\mathrm{~g})+1 / 2 \mathrm{O}_{2}(\mathrm{~g}) \\
& \mathrm{Rate}=k\left[\mathrm{~N}_{2} \mathrm{O}\right]^{0}=k \text { or, } \\
& \frac{\Delta\left[\mathrm{N}_{2} \mathrm{O}\right]}{\Delta t}=k
\end{aligned}
$$

Decomposition of $\mathrm{NH}_{3}(\mathrm{~g})$ in the presence of molybdenum or tungsten is a zero-order reaction.

$$
2 \mathrm{NH}_{3}(\mathrm{~g}) \xrightarrow{M o} \mathrm{~N}_{2}(\mathrm{~g})+3 \mathrm{H}_{2}(\mathrm{~g})
$$

The surface of the catalyst is almost completely covered by $\mathrm{NH}_{3}$ molecules. The adsorption of gas on the surface cannot be changed by increasing the pressure or

## G.C.E. (A/L) CHEMISTRY: UNIT 11 Chemical Kinetics

concentration of $\mathrm{NH}_{3}$. Thus, the concentration of gas phase remains constant although the product is formed. Therefore, this reaction has zero order kinetics.
Other examples for zero order reactions are:
Iodination of acetone in the presence of $\mathrm{H}^{+}(a q)$ ions:

$$
\mathrm{CH}_{3} \mathrm{COCH}_{3}(\mathrm{aq})+\mathrm{I}_{2}(\mathrm{aq}) \xrightarrow{\mathrm{H}^{+}(a q)} \mathrm{ICH}_{2} \mathrm{COCH}_{3}(\mathrm{aq})+\mathrm{HI}(\mathrm{aq})
$$

Experimentally found that the rate equation of this reaction does not containing $\left[I_{2}\right]$ factor, i.e.,

$$
\text { Rate }=k\left[\mathrm{CH}_{3} \mathrm{COCH}_{3}(\mathrm{aq})\right]\left[\mathrm{H}^{+}(\mathrm{aq})\right]
$$

Indicating that the reaction is zero order with respect to [ $\left.\mathrm{I}_{2}(\mathrm{aq})\right]$

## Characteristics of zero order reactions

The concentration of the reactants decreases linearly with time.
The time required for the reaction to be complete, i.e., time at which $[\mathrm{A}]$ is zero is given by;

$$
t_{\text {completion }}=\frac{[\mathrm{A}]_{0}}{k}=(\text { Initial concentration }) /(\text { Rate constant })
$$

## First order reactions

In this class of reactions, the rate of the reaction is proportional to the first power of the concentration of the reactant. For example, considering the same reaction; A $\rightarrow$ products

$$
\text { Rate }=k[\mathrm{~A}]
$$

This takes the form; $y=m x$ and the graph of rate against the concentration will be a straight line going through the origin $(0,0)$ as shown in Figure 1.15(a). The plot of the variation of concentration over the time will be a curve as shown in Figure 1.15(b).

Figure 1.15 (a) Variation of reaction rate over the concentration of the reactant (gradient $=$ rate constant) and (b) Variation of concentration of the reactant over the time for a first-order reaction.

## G.C.E. (A/L) CHEMISTRY: UNIT 11 <br> Chemical Kinetics

Let us consider this in another way.
We can write,

$$
\text { Rate }=k[\mathrm{~A}]
$$

Taking $\log$ of both sides; $\quad \log ($ Rate $)=\log [\mathrm{A}]+\log (k)$

Therefore, the graph of $\log$ (Rate) against $\log [\mathrm{A}]$ will be $\boldsymbol{y}=\boldsymbol{m x} \boldsymbol{x} \boldsymbol{c}$ type having the slope of one (1) and the intercept of $\log (k)$ as shown in Figure 1.17 (will be shown later).

As discussed previously, the rate constant of a first order reaction has only (inverse) time unit. It has no concentration unit. This means that the numerical value of $k$ for a first order reaction is independent of the unit in which concentration is expressed. $\left(\mathrm{k}=\frac{\text { rate }}{\text { concentration }}=\frac{\mathrm{mol} \mathrm{dm}^{-3} \mathrm{~s}^{-1}}{\mathrm{~mol} \mathrm{dm}^{-3}}\right)$ Therefore, even if the concentration unit is changed the numerical value of $k$ for a first order reaction will remain unchanged. However, it would change with the change in time unit. Say, $k$ is $6.0 \times 10^{-3} \mathrm{~min}^{-1}$, then it can also be written as $1.0 \times 10^{-4} \mathrm{~s}^{-1}$.i.e. The numerical value of $k$ has changed.

Following are some examples for the first order reactions.
Decomposition of $\mathrm{H}_{2} \mathrm{O}_{2}(\mathrm{aq})$ in aqueous solution

$$
\mathrm{H}_{2} \mathrm{O}_{2}(\mathrm{aq}) \rightarrow \mathrm{H}_{2} \mathrm{O}(\mathrm{l})+1 / 2 \mathrm{O}_{2}(\mathrm{~g})
$$

Hydrolysis of methyl acetate in the presence of mineral acids
$\mathrm{CH}_{3} \mathrm{COOCH}_{3}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightarrow \mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})+\mathrm{CH}_{3} \mathrm{OH}(\mathrm{aq})$
Inversion of cane sugar in the presence of mineral acids

$$
\mathrm{C}_{12} \mathrm{H}_{22} \mathrm{O}_{11}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \xrightarrow{\mathrm{H}^{+}} \mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}(\mathrm{aq})+\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}(\mathrm{aq})
$$

Decomposition of ammonium nitrite in aqueous solution

$$
\mathrm{NH}_{4} \mathrm{NO}_{2}(\mathrm{aq}) \rightarrow \mathrm{N}_{2}(\mathrm{~g})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

Hydrolysis of diazo derivatives

$$
\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{~N}=\mathrm{NCl}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightarrow \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{OH}(\mathrm{aq})+\mathrm{N}_{2}(\mathrm{~g})+\mathrm{HCl}(\mathrm{aq})
$$

In the cases where gas phase reactions are considered, it is necessary to use pressure terms instead of concentration terms in the rate law. For example, a reaction $\mathrm{A}(\mathrm{g}) \rightarrow \mathrm{B}(\mathrm{g})+\mathrm{C}(\mathrm{g})$ is a first order reaction. If the initial $(\mathrm{at} \mathrm{t}=0)$ pressure of the system is $\mathrm{P}_{1}$ and the pressure of the system changed to $\mathrm{P}_{2}$ after time $t$, it is necessary to understand the way we write the rate law of the reaction.

In this case we can assume that the partial pressure of A is decreased by -x due to its decomposition and hence the pressures built up by each of $B$ and $C$ would be $+x$. Therefore we can construct the system as follows.

|  | $\mathrm{A}(\mathrm{g}) \rightarrow \mathrm{B}(\mathrm{g})+\mathrm{C}(\mathrm{g})$ |  |  |
| :--- | :--- | :---: | :---: |
| Initial | $P_{1}$ | 0 | 0 |
| At time $\boldsymbol{t}$ | $P_{1}-x$ | $x$ | $x$ |

## G.C.E. (A/L) CHEMISTRY: UNIT 11 Chemical Kinetics

Therefore, total pressure at time $t=\left(P_{1}-x\right)+x+x=P_{1}+x=P_{2}$

$$
\begin{gathered}
\therefore x=P_{2}-P_{1} \\
\text { t Pressure of A at } t=P_{1}-x=P_{1}-\left(P_{2}-P_{1}\right)=2 P_{1}-P_{2}
\end{gathered}
$$

Thus these pressure terms can be used for the estimation of orders and rate constants of the reactions.

## Second order reactions

In this class of reactions, the rate of the reaction is proportional to the second power of the concentration of the reactant or if the concentration of the respective reactant is doubled the rate will be quadrupled. For example, considering the same reaction; A $\rightarrow$ products

$$
\text { Rate }=k[\mathrm{~A}]^{2}
$$

This takes the form; $y=m x^{2}$ and the graph of rate against the concentration will be a upward-curve passes through the origin $(0,0)$ as shown in the Figure $1.16(a)$. The variation of concentration against time will be a curve; however, slope would be higher than that for the first order plot as seen in Figure 1.16(b).

(a)

(b)

Figure 1.16 (a) Variation of reaction rate over the concentration of the reactant and (b) Variation of concentration of the reactant over the time for a second-order reaction.

Let us consider this in another way,
We can write,

$$
\text { Rate }=k[\mathrm{~A}]^{2}
$$

Taking $\log$ of both sides; $\quad \log ($ Rate $)=2 \log [\mathrm{~A}]+\log (k)$

Therefore, the graph of $\log$ (rate) against $\log [\mathrm{A}]$ will be $\boldsymbol{y}=\boldsymbol{m} \boldsymbol{x}+\boldsymbol{c}$ type having the slope of two (2) and the intercept of $\log (k)$. As a summary Figure 1.17 compares the above cases in order to understand the differences in zeroth, first and second order reactions easily.

## G.C.E. (A/L) CHEMISTRY: UNIT 11 Chemical Kinetics

Figure 1.17 Comparison of first order, second order and zero order reactions; (a) Variation of reaction rate with concentration. The plot is a horizontal line for the zero order reaction because the rate does not change no matter what the value of [A]. The plot is an upward-sloping line for the first order reaction because the rate is directly proportional to $[\mathrm{A}]$. The plot is an upward-sloping curve for the second order reaction because the rate increases exponentially with [A]. (b) Variation of concentration over time. The decrease in [A] does not change as time goes on for a zero order reaction. The decrease slows down as time goes on for a first order reaction. The decrease is even more for a second-order reaction. (c) Variation of $\log ($ rate $)$ with $\log ($ concentration $)$. The plot is a horizontal line for the zero order reaction. The plot is a straight line with the slope one for the first order reaction and the plot is a straight line with the slope two for a second order reaction.

## Example 1.10

Consider the following first order reaction.

$$
\mathrm{N}_{2} \mathrm{O}_{5}(\mathrm{~g}) \rightarrow 2 \mathrm{NO}_{2}(\mathrm{~g})+1 / 2 \mathrm{O}_{2}(\mathrm{~g})
$$

At 328 K , when the concentration of $\mathrm{N}_{2} \mathrm{O}_{5}(\mathrm{~g})$ was $2.00 \times 10^{-2} \mathrm{~mol} \mathrm{dm}^{-3}$ the rate of the decomposition was found to be $1.00 \times 10^{-2} \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{~s}^{-1}$. Calculate the first order rate constant of the reaction at 328 K .

## Answer

$$
\begin{aligned}
& \text { Rate }=k[\mathrm{~A}]=1.00 \times 10^{-2} \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{~s}^{-1} \\
& \therefore k=\frac{1.00 \times 10^{-2} \mathrm{~mol} \mathrm{dm}}{} \mathrm{~m}^{-3} \mathrm{~s}^{-1} \\
& 2.00 \times 10^{-2} \mathrm{~mol} \mathrm{dm}^{-3}
\end{aligned}=0.50 \mathrm{~s}^{-1}
$$

## Example 1.11

Consider the reaction between oxygen and nitrogen monoxide.

$$
\mathrm{O}_{2}(\mathrm{~g})+2 \mathrm{NO}(\mathrm{~g}) \rightarrow 2 \mathrm{NO}_{2}(\mathrm{~g})
$$

Rate law of the reaction is rate $=k\left[\mathrm{O}_{2(\mathrm{~g})}\right][\mathrm{NO}(\mathrm{g})]^{2}$ at 300 K .

When the concentrations of $\mathrm{O}_{2}(\mathrm{~g})$ and $\mathrm{NO}(\mathrm{g})$ were $1.00 \times 10^{-2}$ and $2.00 \times 10^{-2} \mathrm{~mol} \mathrm{dm}^{-3}$, respectively, the rate was found to be $3.20 \times 10^{-3} \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{~s}^{-1}$ at 300 K . Calculate the rate constant for the reaction at 300 K .

## Answer

$k=\frac{\text { rate }}{\left[\mathrm{O}_{2(\mathrm{~g})}\right][\mathrm{NO}(\mathrm{g})]^{2}}$
$=\frac{3.20 \times 10^{-3} \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{~s}^{-1}}{\left[1.00 \times 10^{-2} \mathrm{~mol} \mathrm{dm}^{-3}\right]\left[2.00 \times 10^{-2} \mathrm{~mol} \mathrm{dm}^{-3}\right]^{2}}$
$k=8.00 \times 10^{2} \mathrm{dm}^{6} \mathrm{~mol}^{-2} \mathrm{~s}^{-1}$

## Example 1.12

Consider the hypothetical reaction given below at a given temperature.

$$
\mathrm{aA}+\mathrm{bB} \rightarrow \mathrm{cC}+\mathrm{dD}
$$

In a particular experiment carried out at a given temperature, the rate of the reaction was found to be $5.00 \times 10^{-4} \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{~s}^{-1}$ when the concentrations of A and B are $1.00 \times 10^{-5} \mathrm{~mol} \mathrm{dm}^{-3}$ and $2.00 \mathrm{~mol} \mathrm{dm}^{-3}$ respectively. It has also been observed that the rate doubles as the concentration of A is doubled. Calculate the rate constant of the reaction.

## Answer

For the reaction we can write the rate law as,

$$
\text { rate }=k[\mathrm{~A}]^{x}[\mathrm{~B}]^{\mathrm{y}}
$$

It is given that the rate doubles as the concentration of $A$ is doubled. Therefore, we can conclude/find that the reaction is first order with respect to A . Next, it is necessary to understand the dependence of rate on the concentration of B , which is much higher than the concentration of $\mathrm{A}\left(1.00 \times 10^{-5} \lll 2.00 \mathrm{~mol} \mathrm{dm}^{-3}\right)$. Thus, it is evident that the reaction rate does not depend on the concentration of $B$, or assuming that [B] remains unchanged during the reaction. Now the rate law of the reaction can be rewritten as,

$$
\begin{aligned}
\text { Rate } & =k^{\prime}[\mathrm{A}] \\
k^{\prime} & =\frac{5.00 \times 10^{-4} \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{~s}^{-1}}{1.00 \times 10^{-5} \mathrm{~mol} \mathrm{dm}^{-3}}=50 \mathrm{~s}^{-1}
\end{aligned}
$$

## G.C.E. (A/L) CHEMISTRY: UNIT 11 Chemical Kinetics

Following example gives an idea about the relation between order and the concentration of the reactants. Consider a hypothetical reaction,

$$
\mathrm{aA}+\mathrm{bB} \rightarrow \mathrm{cC}+\mathrm{dD}
$$

and the rate low of the reaction is given by; Rate $=k[\mathrm{~A}][\mathrm{B}]^{2}$
(a) Consider that the initial concentrations of both A and B are $1.0 \mathrm{~mol} \mathrm{dm}^{-},{ }^{3}$

$$
\operatorname{Rate}_{1}=k[1.0][1.0]^{2} \mathrm{~mol}^{3} \mathrm{dm}^{-9}=k \mathrm{~mol}^{3} \mathrm{dm}^{-9}
$$

If the concentration of $A$ is doubled while keeping the concentration of $B$ constant at $1.0 \mathrm{~mol} \mathrm{dm}^{-3}$,

$$
\operatorname{Rate}_{2}=k[2.0][1.0]^{2} \mathrm{~mol}^{3} \mathrm{dm}^{-9}=2 k \mathrm{~mol}^{3} \mathrm{dm}^{-9}
$$

i.e. The rate is doubled when the concentration of A is doubled revealing that the reaction is first order with respect to A .
(b) If the concentration of $B$ is doubled while keeping the concentration of $A$ constant at $1.0 \mathrm{~mol} \mathrm{dm}^{-3}$,

$$
\text { Rate }_{3}=k[1.0][2.0]^{2} \mathrm{~mol}^{3} \mathrm{dm}^{-9}=4 k \mathrm{~mol}^{3} \mathrm{dm}^{-9}
$$

i.e. The rate is quadrupled when the concentration of $B$ is doubled revealing that the reaction is second order with respect to $B$.

### 1.7.4 Methods to determine the order of a reaction and rate constant (Rate law)

From the above last two examples, when a concentration of one reactant is in large excess compared to the other reactant it has been assumed that the concentration of that reactant can be considered a constant during the course of reaction. This postulate can be used to investigate the kinetics of reactions involving more than one reactant and the experiments can be designed as such.

There are two fundamentally different approaches to this; follow a particular reaction all the way through, and process the results from that single reaction or investigate the change occurred in the initial rate of the reaction as concentrations of the reactants are changed. In the first approach experiments are carried out by keeping the concentrations of all the reactants except one is in large excess. Thus for example, for the reaction:

$$
a \mathrm{~A}+b \mathrm{~B} \rightarrow c \mathrm{C}+d \mathrm{D}
$$

The rate law is: $\quad$ Rate $=k[\mathrm{~A}]^{x}[\mathrm{~B}]^{\mathbf{y}}$

Let B to be in large excess relative to $[\mathrm{A}]_{\mathrm{o}}$, so that $[\mathrm{B}]$ can be considered constant during a course of reaction. Thus we may write:

$$
\text { Rate }=k^{\prime}[\mathrm{A}]^{x}
$$

where:

$$
k^{\prime}=k[\mathrm{~B}]^{y}
$$

## G.C.E. (A/L) CHEMISTRY: UNIT 11 Chemical Kinetics

By taking logarithm of both sides we get:

$$
\log (\text { Rate })=y \log [\mathrm{~A}]+\log \left(k^{\prime}\right)
$$

which is the equation of a straight line and by plotting $\log$ (Rate) against $\log [\mathrm{A}]$ with gradient $\mathbf{y}$ and intercept of $\log (k)$, the order and the rate constant of the reaction would be estimated.

The process can then be repeated by letting A in excess to determine $\boldsymbol{x}$ and $k$.

## Method of initial rates

As we know, the rate laws are not derived from the reaction equation and are derived from experimental data. The method of initial rates is an experimental method to investigate the kinetics of reaction leading to find the rate constant and orders of a given reaction, in which a reaction is run multiple times with different initial concentrations of each reactant. The initial rate of each experiment is compared with the initial concentrations of the reactants to determine its order. The method is most often performed in the following way:

In a simple way of initial rate experiments involve measuring the time taken for some easily measurable or recognizable event that happens very early in a reaction. This could be the time taken for, say, to liberate a given volume of a gas, to from a measurable amount of a precipitate or for a colour change to occur. Further, some titrations can be performed by stopping a reaction after a given period of time.

Then the concentration of one of the components of the reaction is changed, keeping everything else such as the concentrations of other reactants, the total volume of the solution and the temperature and so on constant. Then the time taken for the same event to take place has to be measured with that new concentration. This has to be repeated for a range of concentrations of the substance interested in. It is worth to cover a reasonably wide range of concentrations, taking perhaps five or more different concentrations varying from the original one down to half of it or less.

This means that for each reactant, it is needed to run at least a pair of reactions in which that reactant's concentration is doubled (changed) while all other reactant concentrations and conditions are held constant. This isolates the effect on rate to that single reactant.
Most often one of three things happens to the initial rate when the reactant concentration is doubled:
(a) The rate does not change: This means that the rate is independent of that reactant. The reaction is zero order with respect to that reactant.
(b) The rate doubles: This means that the rate is proportional to the concentration of that reactant. The reaction is first order with respect to that reactant.
(c) The rate quadruples: This means that the rate is proportional to the square of the concentration of that reactant. The reaction is second order with respect to that reactant.

Once the order for each reactant is found, take any of the experiments and substitute in concentration values and the measured rate to determine the numerical value of the rate constant $k$.

## Exploration of the results from initial rate experiments

Consider a simple example of an initial rate experiment in which a gas being produced. This could be a reaction between a metal and an acid, for example, or the catalytic decomposition of hydrogen peroxide. Assume that the volume of the evolved gas being measured with the time and that can be shown as a plot of volume of gas given off against time as shown in the Figure 1.18.

Figure 1.18 Measuring the volume of an evolved gas in an initial rate experiment. (a) Change in volume over the time, volume increases very fast at the beginning and slows down when the reaction progresses. (b) Expanded view of the shaded area of (a) Increase in volume at the very beginning of the reaction is linear and therefore it is possible to measure the time taken to produce a constant volume of gas by varying the concentration of the desired reactant at a given temperature.

We know that a measure of the rate of the reaction at any point is found by measuring the slope of the graph. Since we are interested in the initial rate, it is necessary to find the slope at the very beginning (say at $t \sim 0 \mathrm{~s}$ ). Of course, it is impossible to observe some changes at the time $=0$, and therefore, we measure the time taken for a given/constant change to happen in the system (like a constant volume). However, since the concentration of the species at the very beginning is almost the initial concentration, it is assumed that during the event measured, the change in concentration of that particular reactant is negligible.

In the Figure 1.18(a), variation of volume over time in the entire range shows a curve. By enlarging the circled area, i.e. enlarging the very beginning of the first curve, it can be seen that it is approximately a straight line at that point (Figure 1.18(b)). That is a reasonable approximation once very early stage in the reaction is considered. This can also be obtained by drawing a tangent line to the curve at the $t \sim 0$. The slope in this case is simply $V / t$. Now suppose the experiment is carried out again with different (lower) concentrations of the reagent and the time taken to evolve the same volume of the gas is measured at the very beginning of the reaction as earlier. Following types of graphs as shown in Figure 1.19 would result for the formation of a constant volume of a gas in which different time measurements could be obtained.

Time
Figure 1.19 Measuring time taken to produce a constant volume of a gas with different concentrations of the reactant in an initial rate experiment. When there is no linearity at the beginning of the reaction, gradient of the tangent has to be determined.

From these experiments the initial rates (in terms of volume of gas produced per second) can be deduced as:

Experimet 1: Initial rate ${ }_{1}=V / t_{1}$
Experimet 2: Initial rate $2=V / t_{2}$
In the above two experiments as the time taken to evolve a constant volume $(V)$ of a gas is measured it is easy to compare the initial rates obtained. It is clear from the above two that the initial rate is inversely proportional to the time taken and therefore;

$$
\text { Initial rate } \propto \frac{1}{t}
$$

Thus, normal in experiments of this type, $\frac{1}{t}$ can be used as a measure of the initial rate without any further calculations. Therefore, the initial rates measured by varying concentrations of respective reactant(s) can be used to determine the orders of reactions

## G.C.E. (A/L) CHEMISTRY: UNIT 11 Chemical Kinetics

and finally the value of the rate constant. Following examples give some insight into this type of experiments.

## Example:

Consider a hypothetical reaction at a given temperature:

$$
\mathrm{A}+2 \mathrm{~B} \rightarrow \mathrm{C}+\mathrm{D}
$$

The rate law, expressed in general terms, is

$$
\text { Rate }=k[\mathrm{~A}]^{m}[\mathrm{~B}]^{n}
$$

To find the values of $\mathbf{m}$ and $\mathbf{n}$, a series of experiments was carried out in which one reactant concentration was changed while the other was kept constant. The initial rate measured in each case is shown in the table shown below. Using the data given in the table calculate the values of $\boldsymbol{m}, \boldsymbol{n}$ and $\boldsymbol{k}$.

Table 1.2 Data set for calcultion

| Experiment | Initial $[\mathbf{A}] /$ <br> $\mathbf{m o l ~ d m}^{\mathbf{- 3}}$ | Initial $[\mathbf{B}] /$ <br> $\mathbf{m o l ~ d m}^{-\mathbf{3}}$ | Initial rate/ <br> $\mathbf{m o l ~ d m}^{-3} \mathbf{s}^{\mathbf{- 1}}$ |
| :--- | :--- | :--- | :--- |
| 1 | $2.5 \times 10^{-2}$ | $3.0 \times 10^{-2}$ | $1.75 \times 10^{-3}$ |
| 2 | $5.0 \times 10^{-2}$ | $3.0 \times 10^{-2}$ | $3.50 \times 10^{-3}$ |
| 3 | $2.5 \times 10^{-2}$ | $6.0 \times 10^{-2}$ | $3.50 \times 10^{-3}$ |

1. Finding $m$, the order with respect to $A$

By comparing experiments 1 and 2, in which [A] doubles and [B] is constant, we can obtain m. First, take the ratio of the general rate laws for these two experiments:

$$
\frac{\operatorname{Rate}_{1}}{\operatorname{Rate}_{2}}=\frac{k[\mathrm{~A}]_{1}^{m}[\mathrm{~B}]_{1}^{n}}{k[\mathrm{~A}]_{2}^{m}[\mathrm{~B}]_{2}^{n}}
$$

In experiments 1 and $2,[\mathrm{~B}]_{1}$ and $[\mathrm{B}]_{2}=3.0 \times 10^{-2} \mathrm{~mol} \mathrm{dm}^{-3}$ and $k$ is a constant as the temperature is constant.
Therefore, we can write;

$$
\begin{aligned}
& \frac{\text { Rate }_{1}}{\text { Rate }_{2}}=\frac{[\mathrm{A}]_{1}^{m}}{[\mathrm{~A}]_{2}^{m}} \\
& \frac{1.75 \times 10^{-3} \mathrm{~mol} \mathrm{~m}^{-3} \mathrm{~s}^{-1}}{3.50 \times 10^{-3} \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{~s}^{-1}}=\frac{\left(2.5 \times 10^{-2} \mathrm{~mol} \mathrm{dm}^{-3}\right)^{m}}{\left(5.0 \times 10^{-2} \mathrm{~mol} \mathrm{dm}^{-3}\right)^{m}} \\
& \frac{1}{2}=\left(\frac{1}{2}\right)^{m} \\
& \quad \therefore \boldsymbol{m}=\mathbf{1}
\end{aligned}
$$

Thus, the reaction is first order with respect to A , because when $[\mathrm{A}]$ doubles, the rate doubles.

## G.C.E. (A/L) CHEMISTRY: UNIT 11 <br> Chemical Kinetics

2. Finding $n$, the order with respect to $B$.

Comparing experiments 3 and 1 in which [A] is held constant and [B] doubles:

$$
\frac{\operatorname{Rate}_{1}}{\operatorname{Rate}_{3}}=\frac{k[\mathrm{~A}]_{1}^{m}[\mathrm{~B}]_{1}^{n}}{k[\mathrm{~A}]_{3}^{m}[\mathrm{~B}]_{3}^{n}}
$$

In experiments 1 and $3,[A]_{1}$ and $[A]_{3}=2.5 \times 10^{-2} \mathrm{~mol} \mathrm{dm}^{-3}$ and $k$ is a constant as the temperature is constant.
Therefore, we can write;

$$
\begin{aligned}
& \frac{\text { Rate }_{1}}{\text { Rate }_{3}}=\frac{[\mathrm{B}]_{1}^{n}}{[\mathrm{~B}]_{3}^{n}} \\
& \frac{1.75 \times 10^{-3} \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{~s}^{-1}}{3.50 \times 10^{-3} \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{~s}^{-1}}=\frac{\left(3.0 \times 10^{-2} \mathrm{~mol} \mathrm{dm}^{-3}\right)^{n}}{\left(6.0 \times 10^{-2} \mathrm{~mol} \mathrm{dm}^{-3}\right)^{n}} \\
& \frac{1}{2}=\left(\frac{1}{2}\right)^{n} \\
& \therefore \boldsymbol{n}=\mathbf{1}
\end{aligned}
$$

Thus, the reaction is also first order with respect to $B$, because when [B] doubles, the rate doubles.
Therefore the rate law of the reaction is

$$
\text { Rate }=k[\mathrm{~A}][\mathrm{B}]
$$

The value of k can be obtained by substituting appropriate values in the rate expression as for the experiment 1 ;

$$
\begin{gathered}
1.75 \times 10^{-3} \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{~s}^{-1}=k\left(2.5 \times 10^{-2}\right)\left(3.0 \times 10^{-2}\right) \mathrm{mol}^{2} \mathrm{dm}^{-6} \\
k=\frac{1.75 \times 10^{-3} \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{~s}^{-1}}{7.50 \times 10^{-4} \mathrm{~mol}^{2} \mathrm{dm}^{-6}}=2.3 \mathrm{~mol}^{-1} \mathrm{dm}^{3} \mathrm{~s}^{-1}
\end{gathered}
$$

Note: What would be the initial rate of the above reaction if the concentrations of both $A$ and $B$ are doubled at the same time?
When both [A] and $[\mathrm{B}]$ doubled, the rate should quadruple to $7.00 \times 10^{-3} \mathrm{~mol} \mathrm{dm}{ }^{-3} \mathrm{~s}^{-1}$ and therefore, that confirms the rate law derived from the experiment.

Note especially, that while the order with respect to $B$ is 1 , the coefficient of $B$ in the balanced equation is 2 . Thus, as mentioned earlier, reaction orders must be determined from experiment.

## Example 1.13

Consider the real reaction between oxygen and nitrogen monoxide at 300 K .

$$
\mathrm{O}_{2}(\mathrm{~g})+2 \mathrm{NO}(\mathrm{~g}) \rightarrow 2 \mathrm{NO}_{2}(\mathrm{~g})
$$

The general rate law is,

$$
\text { Rate }=k\left[\mathrm{O}_{2}(\mathrm{~g})\right]^{m}[\mathrm{NO}(\mathrm{~g})]^{n}
$$

Using the data given in the table below derive the rate law of the reaction at 300 K .

| Experiment | $\begin{aligned} & \text { Initial }\left[\mathrm{O}_{2}(\mathrm{~g})\right] \text { or } \\ & {\left[\mathrm{O}_{2}(\mathrm{~g})\right]_{0}} \\ & \mathrm{~mol} \mathrm{dm} \end{aligned}$ | Initial [ $\mathrm{NO}(\mathrm{g})]$ or [ $\mathrm{NO}(\mathrm{g})] 0 /$ $\mathrm{mol} \mathrm{dm}^{-3}$ | Initial rate $\mathrm{mol} \mathrm{dm}^{-3} \mathrm{~s}^{-1}$ |
| :---: | :---: | :---: | :---: |
| 1 | $1.0 \times 10^{-2}$ | $2.0 \times 10^{-2}$ | $3.20 \times 10^{-3}$ |
| 2 | $2.0 \times 10^{-2}$ | $2.0 \times 10^{-2}$ | $6.40 \times 10^{-3}$ |
| 3 | $1.0 \times 10^{-2}$ | $4.0 \times 10^{-2}$ | $12.80 \times 10^{-3}$ |
| 4 | $3.0 \times 10^{-2}$ | $2.0 \times 10^{-2}$ | $9.60 \times 10^{-3}$ |

$\left[\mathrm{O}_{2}(\mathrm{~g})\right]_{0}$ and $[\mathrm{NO}(\mathrm{g})]_{0}$ are the initial concentrations.

## Answer

1. Finding m , the order with respect to $\mathrm{O}_{2}(\mathrm{~g})$.

By comparing experiments 1 and 2, in which $\left[\mathrm{O}_{2}(\mathrm{~g})\right]$ doubles and $[\mathrm{NO}(\mathrm{g})]$ is constant, we can obtain m. First, take the ratio of the general rate laws for these two experiments:

$$
\frac{\text { Rate }_{1}}{\text { Rate }_{2}}=\frac{k\left[\mathrm{O}_{2}\right]_{1}^{m}[\mathrm{NO}]_{1}^{n}}{k\left[\mathrm{o}_{2}\right]_{2}^{m}[\mathrm{NO}]_{2}^{n}}
$$

In experiments 1 and $2,[\mathrm{NO}]_{1}=[\mathrm{NO}]_{2}=2.0 \times 10^{-2} \mathrm{~mol} \mathrm{dm}^{-3}$ and $k$ is a constant as the temperature is constant.

Therefore, we can write;

$$
\begin{gathered}
\frac{\text { Rate }_{1}}{\text { Rate }_{2}}=\frac{\left[\mathrm{O}_{2}\right]_{1}^{m}}{\left[\mathrm{O}_{2}\right]_{2}^{m}} \\
\frac{3.20 \times 10^{-3} \mathrm{~mol} \mathrm{dm}}{}{ }^{-3} \mathrm{~s}^{-1} \\
6.40 \times 10^{-3} \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{~s}^{-1}
\end{gathered}=\frac{\left(1.0 \times 10^{-2} \mathrm{~mol} \mathrm{dm}^{-3}\right)^{m}}{\left(2.0 \times 10^{-2} \mathrm{~mol} \mathrm{dm}^{-3}\right)^{m}}
$$

Thus, the reaction is first order with respect to $\mathrm{O}_{2}$, because when $\left[\mathrm{O}_{2}(\mathrm{~g})\right]$ doubles, the rate doubles.
Experiment 4 also supports the value of $m(m=1)$; rate increases thrice when the concentration is increased by three times.
2. Finding n , the order with respect to $\mathrm{NO}(\mathrm{g})$.

Comparing experiments 1 and 3 in which $\left[\mathrm{O}_{2}\right]$ is held constant and [NO] doubles:

$$
\frac{\text { Rate }_{1}}{\text { Rate }_{3}}=\frac{k\left[\mathrm{O}_{2}\right]_{1}^{m}[\mathrm{NO}]_{1}^{n}}{k\left[\mathrm{O}_{2}\right]_{3}^{m}[\mathrm{NO}]_{3}^{n}}
$$

In experiments 1 and $3,\left[\mathrm{O}_{2}\right]_{1}$ and $\left[\mathrm{O}_{2}\right]_{3}=1.0 \times 10^{-2} \mathrm{~mol} \mathrm{dm}^{-3}$ and k is a constant as the temperature is constant.
Therefore, we can write;

$$
\begin{aligned}
& \frac{\text { Rate }_{1}}{\text { Rate }_{3}}=\frac{[\mathrm{NO}]_{1}^{n}}{[\mathrm{NO}]_{3}^{n}} \\
& \frac{3.20 \times 10^{-3} \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{~s}^{-1}}{12.8 \times 10^{-3} \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{~s}^{-1}}=\frac{\left(2.0 \times 10^{-2} \mathrm{~mol} \mathrm{dm}^{-3}\right)^{n}}{\left(4.0 \times 10^{-2} \mathrm{~mol} \mathrm{dm}^{-3}\right)^{n}} \\
& \frac{1}{4}=\left(\frac{1}{2}\right)^{n} \\
& \therefore \boldsymbol{n}=\mathbf{2}
\end{aligned}
$$

Thus, the reaction is second order with respect to NO, because when [NO] doubles, the rate increases four times.
Therefore the rate law of the reaction is

$$
\text { Rate }=k\left[\mathrm{O}_{2}(\mathrm{~g})\right][\mathrm{NO}(\mathrm{~g})]^{2}
$$

Note: In some cases we may not have exactly simplifying numbers in this calculations. For example if the initial rate of the experiment 1 is $3.10 \times 10^{-3} \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{~s}^{-1}$, then we get $\frac{3.10 \times 10^{-3} \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{~s}^{-1}}{6.40 \times 10^{-3} \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{~s}^{-1}}=0.485$ and hence $0.485=\left(\frac{1}{2}\right)^{m}=(0.500)^{m}$.

This can be solved by taking log as;
$\log (0.485)=m \log (0.500)$

$$
m=\frac{\log (0.485)}{\log (0.500)}=1.04 \text { or } m=\frac{\log (0.500)}{\log (0.500)}=1 \quad(\text { as } 0.485 \sim 0.500)
$$

As $m$ has to be an integer, $m=1$

The value of $k$ can be obtained by substituting appropriate values in the rate expression as for the experiment 1 .

$$
\begin{gathered}
3.20 \times 10^{-3} \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{~s}^{-1}=k\left(1.0 \times 10^{-2}\right)\left(2.0 \times 10^{-2}\right)^{2} \mathrm{~mol}^{3} \mathrm{dm}^{-9} \\
k=\frac{3.20 \times 10^{-3} \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{~s}^{-1}}{4.0 \times 10^{-6} \mathrm{~mol}^{3} \mathrm{dm}^{-9}}=8.00 \times 10^{2} \mathrm{~mol}^{-2} \mathrm{dm}^{6} \mathrm{~s}^{-1}
\end{gathered}
$$

## G.C.E. (A/L) CHEMISTRY: UNIT 11

In addition to the above type of calculations, the data obtained by several experiments can be plotted as a plot of $\frac{1}{t}$ against the varying concentrations of the reactant. If the reaction is first order with respect to that substance, then straight line will result. That's because in a first order reaction, the rate is proportional to the concentration.

If the plot is a curve, then it isn't first order. It might be second order (or some sort of fractional order).

The best way for this analysis with several data of initial rates is constructing a log graph. As previously discussed, for a reaction involving A, with an order of $\boldsymbol{n}$ with respect to A, the rate equation is:

$$
\text { Rate }=k[\mathrm{~A}]^{\mathrm{n}}
$$

Taking the $\log$ of each side of the equation, you get:

$$
\log (\text { Rate })=n \log [A]+\log k
$$

Therefore the plot of $\log$ (Rate) against $\log [\mathrm{A}]$, would give a straight line with slope $n$, that is the order of the reaction. The intercept of the plot is $\log (k)$ and hence $k$ can be obtained.

Figure 1.20 Shapes of graphs that could be obtained from initial rate experiments (Figure 1.17(a) can also be obtained)

Some kind of laboratory experiments can be designed and carried out by measuring time measurements to occur for a constant extent of the reaction and then by plotting the appropriate graphs, the order of the reaction(s) can be deduced. Following are some examples which are included in your practical manual.

## Thiosulphate-acid reaction

Addition of dilute nitric acid $\left(\mathrm{HNO}_{3}\right)$ to sodium thiosulphate $\left(\mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}\right)$ solution at room temperature results in a slow formation of a pale yellow precipitate of sulphur through the following reaction.

$$
\mathrm{Na}_{2} \mathrm{~S}_{2} \mathrm{O}_{3}(\mathrm{aq})+2 \mathrm{HNO}_{3}(\mathrm{aq}) \rightarrow \mathrm{S}(\mathrm{~s})+2 \mathrm{NaNO}_{3}(\mathrm{aq})+\mathrm{SO}_{2}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

In this system, there is a simple, but very effective, way of measuring the time taken for a small fixed amount of sulphur precipitate to form. As a precipitate is formed in the reaction, it is possible to measure the time taken to form a fixed amount of precipitate under different concentrations of reactants at a given temperature as follows.

Keep a flask or small beaker on a piece of paper with a cross mark (X) drawn on it, and then look down through the reaction mixture until the cross disappears. First, put a known amount of thiosulphate solution in to a beaker and then add a small amount of dilute acid solution with known different concentrations and measure the time it takes for the cross to disappear (Detailed experiment is discussed in your practical manual). In this experiment, the actual concentration of the sodium thiosulphate does not have to be known because in each case, its relative concentration can be estimated with the total volume of the reaction mixture. The solution with $40 \mathrm{~cm}^{3}$ of sodium thiosulphate solution plus $10 \mathrm{~cm}^{3}$ of water has a concentration which is $80 \%$ of the original one, for example. The one with $10 \mathrm{~cm}^{3}$ of sodium thiosulphate solution plus $40 \mathrm{~cm}^{3}$ of water has a concentration which is $20 \%$ of the original one.

After collecting data on the time measurements, the data can be plotted as the variation of $1 / \mathrm{t}$ with the thiosulphate concentration and from that the reaction order with respect to the reactant thiosulphate can be deduced. In addition to this, the effect of temperature on the reaction rate could also be investigated as described in the practical manual.

## Iodine clock experiments

There are several reactions given the name "iodine clock". They are all reactions which give iodine as one of the products and help measure the time taken for the formation of constant amount of iodine. This is the simplest of them, because it involves the most familiar reagents. For example, kinetics of the reaction of the oxidation of iodide ions by hydrogen peroxide under acidic conditions can be monitored by such "iodine clock" experiments. In the acidic medium iodide ions reacts with hydrogen peroxide as follows.

$$
\mathrm{H}_{2} \mathrm{O}_{2}(\mathrm{aq})+2 \mathrm{I}^{-}(\mathrm{aq})+2 \mathrm{H}^{+}(\mathrm{aq}) \rightarrow \mathrm{I}_{2}(\mathrm{aq})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

In this reaction the amount of iodine ( $\mathrm{I}_{2}(\mathrm{aq})$ ) produced can be monitored by using starch when a small amount has been formed. Iodine reacts with starch solution to give a deep blue colored complex turning the solution blue. If a little volume (few drops) of starch solution is added to the reaction mixture initially, as soon as the first trace of iodine was formed, the solution would turn blue. However, just the addition of starch will not help to follow the kinetics as the colour change occurs instantaneously. Therefore, another way to remove the iodine produced is used. As iodine also reacts with sodium thiosulphate solution that can be used to consume some iodine produced.

$$
2 \mathrm{~S}_{2} \mathrm{O}_{3}{ }^{2-}(\mathrm{aq})+\mathrm{I}_{2}(\mathrm{aq}) \rightarrow 2 \mathrm{I}^{-}(\mathrm{aq})+\mathrm{S}_{4} \mathrm{O}_{6}{ }^{2-}(\mathrm{aq})
$$

If a very small known amount of sodium thiosulphate solution is added to the reaction mixture (including the starch solution), it will react with the iodine that is initially produced, and so the iodine will not affect the starch and no blue colour is displayed. However, when that small amount of sodium thiosulphate has been used up, there is nothing to stop the next bit of iodine produced from reacting with the starch. The mixture suddenly goes blue and the time taken to appear the blue colour can be measured for different experimental conditions.

In this experiment, effect of changing the hydrogen peroxide concentration, or the iodide ion concentration, or the hydrogen ion concentration - each time, keeping everything else constant would let you find the orders with respect to each reactant taking part in the reaction.

Note that a similar experiment is included in the practical manual to follow the kinetics of the reaction;

$$
2 \mathrm{I}^{-}(\mathrm{aq})+2 \mathrm{Fe}^{3+}(\mathrm{aq}) \rightarrow \mathrm{I}_{2}(\mathrm{aq})+2 \mathrm{Fe}^{2+}(\mathrm{aq})
$$

In addition to the above - mentioned reactions, the method of initial rate can be used to monitor the kinetics of the catalytic decomposition of hydrogen peroxide by monitoring the volume of oxygen gas produced at a given temperature.
Above examples show that the kinetics of reactions can be investigated by carefully designed experiments. It has to be noted that following requirements must be fulfilled once such experiments are carried out.
(i) Controlling the temperature of the system with a good thermostat (this will be learnt during practical) as rates change (exponentially) with temperature.
(ii) Choosing an accurate timing device.
(iii) An appropriate method for determining the concentration of reactant or product. This can be done through a measurement of a rapidly determinable physical property of the reaction mixture.

## Following the course of a single reaction

Rather than doing a whole set of initial rate experiments, information about orders of reaction can also be obtained by following a particular reaction from start to finish.

There are two different ways to do this. Withdraw samples of the mixture at intervals and find out how the concentration of one of the reagents is changing by doing an appropriate titrations. Or by measuring some physical property of the reaction which changes as the reaction proceeds - for example, refractive index, absorbance, etc. Then the set of values obtained for concentration can be plotted against time and the rates of reaction at different points need to be extracted from the graph. Finally, by plotting $\log ($ rate $)$ against $\log$ (concentration) the order of reaction can be estimated.

## Half-life of a reaction ( $\mathbf{t}_{1 / 2}$ )

As the reaction proceeds, the concentration of the reactant(s) decreases and another measure of the rate of reaction relating the concentration to the time is the half-life. The concept of half-life is useful for describing the rough speed of a reaction. The half-life of a reaction is the time it takes for the consumption of reactants by half of the initial amount. In other words, the half-life of a reaction is the time in which the concentration of a reactant is reduced to one half of its initial concentration. It is represented as $\mathbf{t}_{1 / 2}$ and this is affected by temperature. This can be represented by the Figure 1.21.

Figure 1.21 Definition of half-life (for a first order reaction)
For example, consider the first order decomposition of hydrogen peroxide. The table below shows the concentration of $\mathrm{H}_{2} \mathrm{O}_{2}$ in increments of 600 min .

Table 1.3 Concentration of $\mathrm{H}_{2} \mathrm{O}_{2}$ in increments of 600 min

| Time/ $\mathbf{m i n}$ | Number of half-lives | Fraction remaining | $\left[\mathbf{H}_{\mathbf{2}} \mathbf{O}_{\mathbf{2}}\right] / \mathbf{m o l ~ d m}^{\mathbf{- 3}}$ |
| :--- | :--- | :--- | :--- |
| 0 | 0 | 1 | 0.020 |
| 600 | 1 | $1 / 2$ | 0.010 |
| 1200 | 2 | $1 / 4$ | 0.005 |
| 1800 | 3 | $1 / 8$ | 0.0025 |
| 2400 | 4 | $1 / 16$ | 0.0013 |
| 3000 | 5 | $1 / 32$ | 0.00065 |

Note that in the first 600 min , the concentration drops from $0.020 \mathrm{~mol} \mathrm{dm}^{-3}$ to $0.010 \mathrm{~mol} \mathrm{dm}^{-3}$. That is, it drops in half. The half-life of the reaction is therefore 600 min . Then, when another 600 min passes (from $\mathrm{t}=600$ to $\mathrm{t}=1200$ ) and the concentration drops in half again: from $0.010 \mathrm{~mol} \mathrm{dm}^{-3}$ to $0.0050 \mathrm{~mol} \mathrm{dm}^{-3}$ the half-life is still 600 min . Successive half-lives produce reaction mixture with concentration fractions of $1 / 2,1 / 4$, $1 / 8,1 / 16$ and $1 / 32$ as shown in the table.

## G.C.E. (A/L) CHEMISTRY: UNIT 11 Chemical Kinetics

## Half-life of a first order reaction

Half-life of a first order reaction is given by, $\mathbf{t}_{1 / 2}=\frac{0.693}{k} *$
$k$ is the rate constant.
Since k is a constant for a given reaction at a given temperature and the expression does not contains any concentration term, the half-life of a first order reaction is a constant independent of initial concentration of reactant.

This means that if we start with $2.00 \mathrm{~mol} \mathrm{dm}^{-3}$, and of a reactant reacting with first order kinetics and after 20 minute it is reduced to $1.00 \mathrm{~mol} \mathrm{dm}^{-3}$, and the half-life of the reaction will be 20 minutes. In other words, during the first 20 minutes $50 \%$ of the reaction completes, then in 40 minutes $75 \%$, in 60 minutes $87.5 \%$ and so on. This can also be understood from the Figure 1.21.

## Example 1.14

A certain first-order reaction has a half-life of 20.0 minutes.
(i) Calculate $k$ for the reaction.
(ii) How much time is required for this reaction to be $75 \%$ complete?

## Answer

(i) Half-life of a first order reaction is given by $\mathbf{t}_{1 / 2}=\frac{0.693}{\mathrm{k}}$.

$$
\begin{aligned}
& 20.0 \mathrm{~min}=\frac{0.693}{k} \\
& k=\frac{0.693}{20 \min }=3.47 \times 10^{-2} \mathrm{~min}^{-1}
\end{aligned}
$$

(ii) If the reaction is $75 \%$ complete that means there is $25 \%$ of the reactant is left or the reaction has occurred up to the second half life cycle. Therefore, the time taken to complete the reaction by $75 \%$ is two-half-lives, i.e 40 min .

Show that in a first order reaction, time required for completion of $99.9 \%$ is 10 times the half-life $\left(\mathrm{t}_{1 / 2}\right)$ of the reaction.

When $99.9 \%$ is completed the remaining amount is $0.100 \%$ or 0.001
The value of remaining concentration after 10 half-life cycles
Can be written as $\frac{1}{2^{n}}=\frac{1}{2^{10}}=\frac{1}{1024}=0.001$
Therefore, the time required for the completion of $99.9 \%$ of a first order reaction is 10 times the half-life.

## G.C.E. (A/L) CHEMISTRY: UNIT 11 Chemical Kinetics

Half-life of a zero order reaction is given by;

$$
\mathbf{t}_{1 / 2}=\frac{[\mathrm{A}]_{0}}{2 k} *
$$

$[\mathrm{A}]_{0}$ is the initial concentration. Therefore, half-life of the zero-order reaction depends on the initial concentration.

* Derivation of this equation will not be tested at the G. C. E. (A/L) Chemistry examination.

### 1.8 The effect of the physical nature (surface area) on the reaction rate

In the section 1.1 a little description on the effect of the physical nature of the reactant on the rate has been given. When the reactions involve solid reactants, increasing the surface area by turning the solid into a fine powder enhances the rate of reaction due the increase in the number of collisions between reacting particles.

As described earlier, rates of reactions depend on the physical nature as Gaseous state > Liquid state > Solid state. The reaction rate of a heterogeneous reaction depends on the surface area of the more condensed phase. In the case of solid reactant, the more finely powdered solid reacts faster than the same mass present as a single lump because the powdered solid has a greater surface area than the single lump.

For example in the reaction between calcium carbonate and hydrochloric acid you can observe in the laboratory that powdered calcium carbonate reacts much faster with dilute hydrochloric acid than the same mass of marble or limestone in lumps.

In the catalytic decomposition of hydrogen peroxide solid manganese(IV) oxide is often used as the catalyst. Oxygen is given off much faster if the catalyst is present as a powder than when the same mass of it is present as granules.

In these cases with increasing surface area of the solid, the frequency of collisions increases and the rate of the reaction thus increases.

For example, the reaction between magnesium metal and a dilute hydrochloric acid involves collision between magnesium atoms and hydrogen ions. The effect of surface area can be understood by the Figure 1.22.

Figure 1.22 Effect of particle size on the reaction rate; (a) A particle has a little area to collide with the reactant molecules, molecules collide only with the outer surface. (b) When the solid sample with the same number of atoms is powdered to fine particles, surface area for the collisions with reactant molecules increases and hence the rate of reaction.

### 1.9 Effect of catalysts on the rate of reactions

Increasing the rate of a reaction has many advantages in industry. Higher temperatures can speed up a reaction, but energy for industrial processes is costly and many organic and biological substances are heat sensitive. More commonly, by far, a reaction is accelerated by a catalyst, a substance that increases the rate without being consumed. Thus, only a small, non stoichiometric amount of the catalyst is required to speed the reaction.

A catalyst is a substance that accelerates a reaction but undergoes no net chemical change. It functions by providing an alternative path with lower activation energy of the reaction and avoids the slow, rate-determining step of the unanalyzed reaction, and results in a higher reaction rate at the same temperature.

As we know, there are two basic types of catalysts namely heterogeneous and homogeneous catalyst. Heterogeneous catalyst is in a different phase (for example, a solid catalyst for a gas-phase reaction). A homogeneous catalyst is a one that is in the same phase as the reaction mixture (for example, acid catalyzed reactions in aqueous solution).

The following examples elaborates the function of a catalyst on the reaction rate. The activation energy for the decomposition of hydrogen peroxide in solution is $76 \mathrm{~kJ} \mathrm{~mol}^{-1}$ and the reaction is slow at room temperature. When a little amount of iodide ions is added, the activation energy falls to $57 \mathrm{~kJ} \mathrm{~mol}^{-1}$, and the rate constant increases by a factor of 2000 .

In addition, enzymes (categorized as biological catalysts), are very specific and can have a dramatic effect on the reactions they control. The activation energy for the acid

## G.C.E. (A/L) CHEMISTRY: UNIT 11

hydrolysis of sucrose is $107 \mathrm{~kJ} \mathrm{~mol}^{-1}$ but the enzyme saccharase reduces it to $36 \mathrm{~kJ} \mathrm{~mol}^{-1}$, corresponding to an acceleration of the reaction by a factor of 1012 at body temperature (310 K).

There are some substances which decrease the rate of reaction and such substances are called inhibitors. Obviously, the substances accelerating the rate will be a catalyst. Catalyst are generally foreign substances but sometimes one of the product formed may act as a catalyst. Such a catalyst is called an "auto catalyst" and the phenomenon is called auto catalysis. The function of the catalyst on the reaction rate can be depicted as illustrated in the Figure 1.23

(a)

(b)

Figure 1.23 Comparison of the reaction profiles with and without a catalyst. The addition of a catalyst to a reaction increases the rate by providing a new, lower-energy alternative pathway. (a) Reaction goes through a different mechanism and (b) for example reaction goes through two transition states.

In a chemical reaction collisions result products only if the particles collide with a certain minimum energy or the activation energy for the reaction. The position of activation energy can be marked on a Maxwell-Boltzmann distribution curve as illustrated in Figure 1.24(a).

## G.C.E. (A/L) CHEMISTRY: UNIT 11 Chemical Kinetics

Figure 1.24 Comparison of Maxwell - Boltzmann distributions with and without a catalyst at 300 K (same temperature). The addition of a catalyst to a reaction increases the rate by increasing the fraction of molecules having enough energy to react through an alternative pathway by increasing the collision frequency and hence the rate of the reaction.

Only those particles represented by the area to the right of the activation energy will react when they collide. The great majority does not have enough energy, and will simply bounce apart. Therefore, to increase the rate of a reaction it is necessary to increase the number of effective collisions by increasing the fraction of molecules with enough energy. In one way, this can be done by providing an alternative pathway for the reaction to happen with lower activation energy. In other words, the activation energy should be moved to the lower energy side (left) of the Maxwell Boltzmann distribution as shown in Figure 1.24(b). Adding a catalyst to a reaction has exactly this effect on activation energy. i.e. a catalyst provides an alternative path for the reaction with a lower activation energy compared to the un-catalyzed reaction as depicted in Figure 1.23.

It is very important to note that;
"A catalyst provides an alternative path for the reaction with lower activation energy." It does not "lower the activation energy of the reaction".

This means that the original value of the activation energy of the reaction remains the same and the new catalyzed-path has lower activation energy. It is just like going through a tunnel without climbing a mountain.

### 1.10 Uses of reaction mechanisms to describe the rate of chemical reactions

In any chemical reaction or change, some bonds are broken and new bonds are formed. Usually, these changes such as bond breaking/ formation and rearrangements are too complicated to happen simply in one stage. Instead, the reaction may involve a series of steps one after the other. A reaction mechanism describes the one or more steps involved in the reaction in a way which makes it clear exactly how the various bonds are broken and formed.

A chemical reaction that takes place in one and only one step i.e., all that occurs in a single step is called an elementary reaction.

A chemical reaction occurring in a sequence of two or more steps is called a multi-step or complex reaction. As described above, the sequence of steps through which a multistep reaction takes place is called the reaction mechanism. Each step in a mechanism is an elementary reaction. Reaction mechanisms cannot be calculated or predicted; instead, all reaction mechanisms must be determined experimentally.

Therefore, a chemical reaction in which one or more chemical species react directly to form products in a single step reaction and with a single transition state is called an elementary reaction. In this elementary reaction the molecules collide exactly as the stoichiometric equation of the reaction.

Further, in an elementary reaction no reaction intermediates are involved. Also their presence is not a requirement to describe the chemical reaction on a molecular scale.

### 1.10.1 Molecularity of a reaction

The molecularity of an elementary reaction is defined as the minimum number of molecules, atoms or ions of the reactant(s) required for the reaction to occur and is equal to the sum of the stoichiometric coefficients of the reactants in the balanced chemical equation.

In general, molecularity of a simple reactions is equal to the sum of the number of molecules of reactants involved in the balanced stoichiometric equation.

When multi-step reaction mechanism is written, the minimum number of reacting particles (molecules, atoms or ions) that comes together or collide in the rate determining step to form a product or products is called the molecularity of a reaction.

Therefore, chemical reactions can be categorized simply by the number of reacting species in an elementary step. A reaction is unimolecular when only a single reactant molecule is involved and is bimolecular when two reactant molecules are involved. For example, in a unimolecular reaction, a single molecule decomposes itself or changes its atoms into a new arrangement, as in the isomerization of cyclopropane to propene. In

## G.C.E. (A/L) CHEMISTRY: UNIT 11 <br> Chemical Kinetics

a bimolecular reaction, a pair of molecules collides and exchange energy while atoms or groups of atoms undergo some other kind of change getting converted into a product or products.

Molecularity is a theoretical concept; it cannot be zero, negative, fractional, infinite and imaginary.

Consider a following reaction in which a bond breaking step involves a single entity breaking up into two pieces. The C-O bond breaks. A single reactant forms two products. Because only one reactant molecule is involved, this step is unimolecular.

The following bond forming step which involves bringing two molecular fragments together to form a single product, a C-O bond is formed. Two reactants form a single product. Because two reactant molecules are involved, this step is bimolecular.

Usually, there are few reactions with termolecular elementary behaviour as the collision of three molecules at the same time is somewhat difficult (However, such reactions occur through multi steps).

### 1.10.2 Examples of single step reactions

Many chemical reactions are simple events that occur in a single step. Acid-base reactions mostly occur in a single step. The protonation of ammonia by a hydronium ion involves the transfer of an $\mathrm{H}^{+}$ion from $\mathrm{H}_{3} \mathrm{O}^{+}$to $\mathrm{NH}_{3}$. This single step is a concerted bond-breaking and forming process.

$$
\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})+\mathrm{NH}_{3}(\mathrm{aq}) \rightarrow \mathrm{H}_{2} \mathrm{O}(\mathrm{l})+\mathrm{NH}_{4}^{+}(\mathrm{aq})
$$

The reaction occurs via a single step involving two species and is called as bimolecular elementary reaction.

The decomposition of $\mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g})$ is a single bond breaking step.

$$
\mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g}) \rightarrow 2 \mathrm{NO}_{2}(\mathrm{~g})
$$

The reaction occurs via a single step involving one species and is called as unimolecular elementary reaction.

## G.C.E. (A/L) CHEMISTRY: UNIT 11 Chemical Kinetics

Followings examples show some elementary reactions with different molecularities.
Table 1.4 Elementary reactions with different molecularities

| Reaction | Molecularity |
| :--- | :--- |
| $\mathrm{PCl}_{5} \rightarrow \mathrm{PCl}_{3}+\mathrm{Cl}_{2}$ | Unimolecular |
| $2 \mathrm{HI} \rightarrow \mathrm{H}_{2}+\mathrm{I}_{2}$ | Bimolecular |
| $\mathrm{NO}+\mathrm{O}_{3} \rightarrow \mathrm{NO}_{2}+\mathrm{O}_{2}$ | Bimolecular |
| $2 \mathrm{SO}_{2}+\mathrm{O}_{2} \rightarrow 2 \mathrm{SO}_{3}$ | Termolecular |
| $2 \mathrm{CO}+\mathrm{O}_{2} \rightarrow 2 \mathrm{CO}_{2}$ | Termolecular |
| $2 \mathrm{FeCl}_{3}+\mathrm{SnCl}_{2} \rightarrow \mathrm{SnCl}_{2}+2 \mathrm{FeCl}_{2}$ | Termolecular |

There are some chemical reactions whose molecularity appears to be more than three from stoichiometric equations, e.g.
$4 \mathrm{HBr}(\mathrm{aq})+\mathrm{O}_{2}(\mathrm{~g}) \rightarrow 2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})+2 \mathrm{Br}_{2}(\mathrm{l})$
$2 \mathrm{MnO}_{4}^{-}(\mathrm{aq})+16 \mathrm{H}^{+}(\mathrm{aq})+5 \mathrm{C}_{2} \mathrm{O}_{4}{ }^{2-}(\mathrm{aq}) \rightarrow 2 \mathrm{Mn}^{2+}(\mathrm{aq})+10 \mathrm{CO}_{2}(\mathrm{~g})+8 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})$
In the first reaction molecularity seems to be ' 5 ' and in the second reaction molecularity seems to be ' 23 '. Such reactions do not occur in a single step and involve two or more steps; each step has its own molecularity not greater than three. Following describes the basic features of reactions which occurs through multistep.

### 1.10.3 Multistep reactions

Chemical processes that occur in a series of elementary steps has their own set of rules.
(i) The overall reaction is the sum of the elementary reaction steps.
(ii) A species that is formed in one step and then used up in a later step is an intermediate.
(iii) A species that is used in one step and increase the rate of the reaction, then regenerated in a later step is acting as a catalyst.
(iv) Neither intermediates nor catalysts are seen in the overall reaction rate law.

## Example 1:

The decomposition of ozone takes place in two steps.
Step 1: $\quad \mathrm{O}_{3}(\mathrm{~g}) \rightarrow \mathrm{O}_{2}(\mathrm{~g})+\mathrm{O}(\mathrm{g})$; unimolecular, bond breaking
Step 2: $\quad \mathrm{O}_{3}(\mathrm{~g})+\mathrm{O}(\mathrm{g}) \rightarrow 2 \mathrm{O}_{2}(\mathrm{~g})$ : bimolecular, bond forming and breaking

As learned in Unit 5, the idea of adding a series of reactions to give a net reaction is used here to determine the overall reaction that takes place in a series of steps.
In this case, $\mathrm{O}(\mathrm{g})$ is present on both sides.

Step 1: $\quad \mathrm{O}_{3}(\mathrm{~g}) \rightarrow \mathrm{O}_{2}(\mathrm{~g})+\mathrm{O}(\mathrm{g})$
Step 2: $\quad \mathrm{O}_{3}(\mathrm{~g})+\mathrm{O}(\mathrm{g}) \rightarrow 2 \mathrm{O}_{2}(\mathrm{~g})$

$$
2 \mathrm{O}_{3}(\mathrm{~g})+\mathrm{O}(\mathrm{~g}) \rightarrow 3 \mathrm{O}_{2}(\mathrm{~g})+\mathrm{O}(\mathrm{~g})
$$

$\therefore$ Overall reaction: $\mathbf{2} \mathbf{O}_{3}(\mathrm{~g}) \rightarrow \mathbf{3} \mathbf{O}_{2}(\mathrm{~g})$
In this example, it can be seen that the $\mathrm{O}(\mathrm{g})$ atom formed in the step 1 is consumed in the step 2 and it doesn't appear in the overall reaction. That doesn't mean that it does not exist at least for a little while. A chemical species that is formed in one step of a mechanism and then used in a later step is called an intermediate. Intermediates never appear in the overall reaction equation. Sometimes they can be observed while the reaction progresses, but other times they are formed and used up so quickly and are not seen.

## Example 2:

The decomposition of hydrogen peroxide in the presence of iodide ion occurs in two steps.
Step 1. $\quad \mathrm{H}_{2} \mathrm{O}_{2}(\mathrm{aq})+\mathrm{I}^{-}(\mathrm{aq}) \rightarrow \mathrm{IO}^{-}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})$; bimolecular
Step 2. $\mathrm{IO}^{-}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}_{2}(\mathrm{aq}) \rightarrow \mathrm{I}^{-}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})+\mathrm{O}_{2}(\mathrm{~g}):$ bimolecular
$\therefore$ Overall reaction

$$
2 \mathrm{H}_{2} \mathrm{O}_{2}(\mathrm{aq}) \rightarrow 2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})+\mathrm{O}_{2}(\mathrm{~g})
$$

In this case, the $\mathrm{IO}^{-}(\mathrm{aq})$ ion is formed in the first step and then consumed in the second step. $\mathrm{IO}^{-}(\mathrm{aq})$ is an intermediate in this reaction. Conversely, $\mathrm{I}^{-}(\mathrm{aq})$ ion is used in the first step and then regenerated in the second step. Therefore, $\mathrm{I}^{-}(\mathrm{aq})$ act as a catalyst in this reaction

## Example 3:

Chlorofluorocarbons break down in the upper atmosphere to give chlorine atoms. These are involved in the breakdown of ozone via the following mechanism.

Step 1.
$\mathrm{Cl}(\mathrm{g})+\mathrm{O}_{3}(\mathrm{~g}) \rightarrow \mathrm{ClO}(\mathrm{g})+\mathrm{O}_{2}(\mathrm{~g})$
Step 2. $\quad \mathrm{ClO}(\mathrm{g})+\mathrm{O}_{3}(\mathrm{~g}) \rightarrow \mathrm{Cl}(\mathrm{g})+\mathrm{O}_{2}(\mathrm{~g})$

Overall reaction: $\quad 2 \mathrm{O}_{3}(\mathrm{~g}) \rightarrow 2 \mathrm{O}_{2}(\mathrm{~g})$
Reactions in step 1 and 2 are both bimolecular. $\mathrm{Cl}(\mathrm{g})$ is a reactant in the Step 1, but is regenerated in Step 2. Cl is therefore a catalyst. ClO is generated in Step 1, but is consumed in Step 2. ClO is therefore an intermediate.

## G.C.E. (A/L) CHEMISTRY: UNIT 11 Chemical Kinetics

### 1.10.4 The rate laws of elementary reactions

The rate law for elementary reactions can deduced directly from their molecularity. For example, the rate law of a unimolecular elementary reaction is first-order with respect to the reactant. Consider the reaction where P denotes products (several different species may be formed).

$$
\begin{gathered}
\mathrm{A} \rightarrow \mathrm{P} \\
\text { Rate }=-\frac{\Delta[\mathrm{A}]}{\Delta t}=k[\mathrm{~A}]
\end{gathered}
$$

A unimolecular elementary reaction is first-order because the number of A molecules that decays in a short interval is proportional to the number available to decay. Therefore the rate of decomposition of A is proportional to its molar concentration.

An elementary bimolecular reaction has a second-order rate law:

$$
\begin{gathered}
2 \mathrm{~A} \rightarrow \mathrm{P} \\
\text { Rate }=k[\mathrm{~A}]^{2}
\end{gathered}
$$

Or we can write the reaction as;

$$
\begin{gathered}
\mathrm{A}+\mathrm{B} \rightarrow \mathrm{P} \\
\text { Rate }=k[\mathrm{~A}][\mathrm{B}]
\end{gathered}
$$

A bimolecular elementary reaction is second order because its rate is proportional to the rate at which the reactant species meet, which in turn is proportional to their concentrations. Therefore, if we consider that a reaction is a single-step, bimolecular process, we can write down the rate law.

Note that the converse of this rule does not follow, that is, for example second order rate law does not imply that the reaction is bimolecular. Also, care must be taken to ensure that the reaction /step that we are considering is really elementary. For example, the reaction
$\mathrm{H}_{2}(\mathrm{~g})+\mathrm{I}_{2}(\mathrm{l}) \rightarrow 2 \mathrm{HI}(\mathrm{g})$ may look simple, but it is not elementary, and in fact, it has a very complex reaction mechanism, and hence the rate law cannot be deduced by merely looking the reaction.

With the above descriptions, for an elementary reaction of the general type;

$$
\mathrm{aA}+\mathrm{bB} \rightarrow \mathrm{cC}+\mathrm{dD}
$$

rate law is written as,

$$
\text { Rate }=k[\mathrm{~A}]^{\mathrm{a}}[\mathrm{~B}]^{\mathrm{b}}
$$

The order of an elementary reaction with respect to a given reactant is exactly same as the stoichiometric coefficient. Therefore, for the above elementary reaction, order with respect to the reactant A is $\boldsymbol{a}$ and the order with respect to the reactant B is $\boldsymbol{b}$. The overall order of the reaction is $(\boldsymbol{a}+\boldsymbol{b})$.

It is very important to understand the difference between molecularity and reaction order: The reaction order is an empirical quantity, and obtained from the experimental rate law.
The molecularity refers to an elementary reaction proposed as an individual step in a mechanism.

The following table summarizes some examples.

Table 1.5 Summary of molecularity

| Molecularity | Elementary step | Rate law |
| :--- | :--- | :--- |
| Unimolecular | $\mathrm{A} \rightarrow$ Products | Rate $=\mathrm{k}[\mathrm{A}]$ |
| Bimolecular | $\mathrm{A}+\mathrm{A} \rightarrow$ Products | Rate $=\mathrm{k}[\mathrm{A}]^{2}$ |
| Bimolecular | $\mathrm{A}+\mathrm{B} \rightarrow$ Products | Rate $=\mathrm{k}[\mathrm{A}][\mathrm{B}]$ |
| Termolecular | $\mathrm{A}+\mathrm{A}+\mathrm{A} \rightarrow$ Products | Rate $=\mathrm{k}[\mathrm{A}]^{3}$ |
| Termolecular | $\mathrm{A}+\mathrm{A}+\mathrm{B} \rightarrow$ Products | Rate $=\mathrm{k}[\mathrm{A}]^{2}[\mathrm{~B}]$ |
| Termolecular | $\mathrm{A}+\mathrm{B}+\mathrm{C} \rightarrow$ Products | Rate $=\mathrm{k}[\mathrm{A}][\mathrm{B}][\mathrm{C}]$ |

### 1.10.5 Reaction mechanisms and the rate law

As described earlier, a species acting as an intermediate or a catalyst does not appear in the rate law. Then it is necessary to understand how the rate law is derived for such systems. Usually, in a mechanism there are some steps that occur very slowly and some other steps that occur very rapidly. The overall rate of a reaction is controlled by the rate of the slowest step. The slowest step of a reaction is known as the rate determining step (RDS). Therefore, in experiments, when the rates are measured, the rate of the rate determining step is actually measured as long as there is a lot of differences among the rates of the various steps.

Consider the following example; in which the reaction occurs in two steps. First the reactant A is transformed into another species B; then in the next step it acts as a reactant which is transformed into the desired product P .

$$
\begin{gathered}
A \xrightarrow{k_{1}} \mathrm{~B} \\
\mathrm{~B} \xrightarrow{k_{2}} \mathrm{P}
\end{gathered}
$$

$k_{1}$ and $k_{2}$ are the rate constants of respective steps.
Assume that $k_{2} \gg k_{1}$. In such a case, whenever a molecule B is formed, it decays rapidly to $P$ indicating that the rate of the reaction depends only on the first step and that the step would be the rate determining step of the reaction.

Consider another example in which the reaction $\mathrm{NO}_{2}(g)+\mathrm{CO}(g) \rightarrow \mathrm{NO}(g)+\mathrm{CO}_{2}(g)$ occurs through following mechanism.

$$
\begin{aligned}
& \mathrm{NO}_{2}(g)+\mathrm{NO}_{2}(g) \xrightarrow{k_{1}} \mathrm{NO}_{3}(g)+\mathrm{NO}(g): \text { slow; rate determining step } \\
& \mathrm{NO}_{3}(g)+\mathrm{CO}(g) \xrightarrow{k_{2}} \mathrm{NO}_{2}(g)+\mathrm{CO}_{2}(g): \text { fast }
\end{aligned}
$$

In this reaction the first step is the rate determining step and hence we can say that the rate of reaction depends only on the rate constant $k_{1}$. This can further be proven from the experiments in determining the empirical rate law of the reaction. The empirical rate law of the reaction is

$$
\text { Rate }=k\left[\mathrm{NO}_{2}\right]^{2}
$$

i.e. the reaction $\mathrm{NO}_{2}(g)+\mathrm{CO}(g) \rightarrow \mathrm{NO}(g)+\mathrm{CO}_{2}(g)$ is $2^{\text {nd }}$ order with respect to $\mathrm{NO}_{2}(g)$ and zero-order with respect to $\mathrm{CO}(\mathrm{g})$.

In the mechanism given above $\mathrm{NO}_{3}$ functions as a reaction intermediate, which is formed and used up during the reaction. Even though it does not appear in the overall balanced equation, a reaction intermediate is essential for the reaction to occur. Intermediates are less stable than the reactants and products.
Rate laws for the two elementary steps written above are;

$$
\begin{gathered}
\text { Rate }_{1}=k_{1}\left[\mathrm{NO}_{2}\right]^{2} \\
\text { Rate }_{2}=k_{2}\left[\mathrm{NO}_{3}\right][\mathrm{CO}]
\end{gathered}
$$

Three key points to notice about this mechanism are
(i) If $k_{1}=k$, the rate law for the rate-determining step (step 1) becomes identical to the observed rate law.
(ii) Because the first step is slow, $\left[\mathrm{NO}_{3}\right]$ is low. As soon as any $\mathrm{NO}_{3}$ forms, it is consumed by the fast second step, so the reaction takes as long as the first step does.
(iii) CO does not appear in the rate law (reaction order $=0$ ) because it takes part in the mechanism after the rate-determining step.

## Example:

Consider the reaction between nitrogen dioxide and fluorine as an example:

$$
2 \mathrm{NO}_{2}(g)+\mathrm{F}_{2}(g) \rightarrow 2 \mathrm{NO}_{2} \mathrm{~F}(g)
$$

The experimental rate law is that it is first order in $\mathrm{NO}_{2}$ and in $\mathrm{F}_{2}$.
$\therefore$ Rate $=k\left[\mathrm{NO}_{2}(\mathrm{~g})\right]\left[\mathrm{F}_{2}(\mathrm{~g})\right]$
The accepted mechanism is

$$
\begin{aligned}
& \text { Step 1; } \mathrm{NO}_{2}(g)+\mathrm{F}_{2}(g) \rightarrow \mathrm{NO}_{2} \mathrm{~F}(g)+\mathrm{F}(g): \text { slow; rate determining } \\
& \text { Step 2; } \mathrm{NO}_{2}(g)+\mathrm{F}(g) \rightarrow \mathrm{NO}_{2} \mathrm{~F}(g) \quad: \text { fast }
\end{aligned}
$$

Note that here the free fluorine atom is a reaction intermediate.
Let us consider the mechanism and how the rate law of the reaction is explained. Sum of the two elementary reaction steps is the overall balanced equation.

## G.C.E. (A/L) CHEMISTRY: UNIT 11 Chemical Kinetics

$$
\begin{array}{ll}
\text { Step 1; } & \mathrm{NO}_{2}(g)+\mathrm{F}_{2}(g) \rightarrow \mathrm{NO}_{2} \mathrm{~F}(g)+\mathrm{F}(g) \\
\text { Step 2; } & \mathrm{NO}_{2}(g)+\mathrm{F}(g) \rightarrow \mathrm{NO}_{2} \mathrm{~F}(g)
\end{array}
$$

Overall reaction: $\quad \mathbf{2 N O}_{2}(g)+\mathbf{F}_{2}(g) \rightarrow \mathbf{2 N O}_{2} \mathbf{F}(g)$

And both steps are bimolecular.
The rate laws for the elementary steps are:

$$
\begin{aligned}
& \operatorname{Rate}_{1}=k_{1}\left[\mathrm{NO}_{2}(\mathrm{~g})\right]\left[\mathrm{F}_{2}(\mathrm{~g})\right] \\
& \operatorname{Rate}_{2}=k_{2}\left[\mathrm{NO}_{2}(\mathrm{~g})\right][\mathrm{F}(\mathrm{~g})]
\end{aligned}
$$

It can be seen that the step 1 is the rate-determining step, and with $k_{1}=k$, it is the same as the overall rate law.

In this mechanism it has to be noted that the second molecule of $\mathrm{NO}_{2}$ is involved after the rate-determining step, so it does not appear in the overall rate law.

From the above examples it can be noted that though the reaction proceeds through several steps, rate law of the reaction follows the rate determining step (slowest step) of the mechanism.

Consider the reaction between 2-bromo-2-methylpropane with hydroxide $\left(\mathrm{OH}^{-}\right)$ions:

$$
\left(\mathrm{CH}_{3}\right)_{3} \mathrm{CBr}+\mathrm{OH}^{-} \rightarrow\left(\mathrm{CH}_{3}\right)_{3} \mathrm{COH}+\mathrm{Br}^{-}
$$

In the overall reaction the bromine atom is replaced by an OH group.
The first step that happens is that the carbon-bromine bond breaks to give ions via a unimolecular reaction;

$$
\left(\mathrm{CH}_{3}\right)_{3} \mathrm{CBr} \rightarrow\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}^{+}+: \mathrm{Br}^{-} \text {: slow }
$$

Carbon-bromine bonds are reasonably strong, so this is a slow change. If there is a high concentration of hydroxide ions, the positive ions will combine with them and this step of the reaction will be very fast. A new covalent bond is made between the carbon and the oxygen, using one of the lone pairs on the oxygen atom via a bimolecular (fast) reaction;

$$
\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}^{+}+: \mathrm{OH}^{-} \rightarrow\left(\mathrm{CH}_{3}\right)_{3} \mathrm{COH}: \text { fast }
$$

The mechanism shows that the reaction takes place in two steps and describes exactly how those steps happen in terms of bonds being broken or made. It also shows that the steps have different rates of reaction; one slow and one fast.

The emperical rate law of the above reaction has been found to be as follows,

$$
\text { Rate }=k\left[\left(\mathrm{CH}_{3}\right)_{3} \mathrm{CBr}\right]
$$

The reaction is first order with respect to the $\left(\mathrm{CH}_{3}\right)_{3} \mathrm{CBr}$, and zero order with respect to the hydroxide ions. The concentration of the hydroxide ions does not affect the rate of the overall reaction.

If the hydroxide ions were taking part in the slow step of the reaction, increasing their concentration would speed up the reaction. Since its concentration does not seem to matter, they must be taking part in a later fast step.

Increasing the concentration of the hydroxide ions will speed up the fast step, but that will not not have a noticeable effect on the overall rate of the reaction as that is governed by the speed of the slow step.

## Example: Predicting a suitable mechanism

Suppose an elementary bimolecular reaction between A and B which was experimentally found to be first order with respect to both A and B.
So the rate equation is:
Rate $=k[\mathrm{~A}][\mathrm{B}]$
Let us consider the following two mechanisms;
Mechanism 1

$$
\begin{aligned}
& \mathrm{A} \rightarrow \mathrm{C}+\mathrm{D} ; \text { slow } \\
& \mathrm{B}+\mathrm{C} \rightarrow \mathrm{E} ; \text { fast }
\end{aligned}
$$

Mechanism 2

$$
\mathrm{A}+\mathrm{B} \rightarrow \mathrm{D}+\mathrm{E} ; \text { slow }
$$

In this case, the reaction is first order with respect to both $A$ and $B$, so one molecule of each must be taking part in the slow step. That means, mechanism 2 is the possible one.

Mechanism 1 must be wrong. One molecule of A is taking part in the slow step, but no B. The rate equation for that would be:

Rate $=k[\mathrm{~A}]$

### 1.10.6 Consecutive (elementary) reactions

As noted from the above reaction steps/mechanisms, the reaction which goes through an intermediate can be expressed as,

$$
\mathrm{A} \xrightarrow{k_{1}} \mathrm{I} \xrightarrow{k_{2}} \mathrm{P}
$$

The above reaction is defined as a consecutive unimolecular reaction because one reactant is involved in each step and the first step is the rate determining step of the reaction. For such a process:
(i) The concentration of A decreases through unimolecular decomposition of A, and is not replenished. Thus we have the rate equation

$$
\text { Rate }=-k_{1}[\mathrm{~A}]
$$

## G.C.E. (A/L) CHEMISTRY: UNIT 11 <br> Chemical Kinetics

(ii) The intermediate I is formed from A at a rate $k_{l}[\mathrm{~A}]$, and decreases through decay to P at rate $k_{2}[\mathrm{I}]$. This event happens very fast.
(iii) The product P is formed from I at a fast rate $k_{2}[\mathrm{I}]$, and it does not decrease.

Therefore, from these it can be simply noted that
(i) The concentration of the reactant A decreases with time;
(ii) The concentration of the intermediate I rises to a maximum and then falls to zero within a short time interval;
(iii) The concentration of the product P rises from zero to some value depending on the stoichiometry of the reaction.

These can be illustrated as shown in the Figure 1.25.

Figure 1.25 The concentrations of $\mathrm{A}, \mathrm{I}$, and P in the consecutive reaction $A \xrightarrow{\mathrm{k}_{1}} \mathrm{I} \xrightarrow{\mathrm{k}_{2}} \mathrm{P}$. Intermediate I is formed and consumed in the next step making its concentration zero with the time.

We can look at the above in another direction as follows.
The reaction $\mathrm{A} \xrightarrow{k_{1}} \mathrm{I} \xrightarrow{k_{2}} \mathrm{P}$ occurs in two steps.

| Step 1; | $\mathrm{A} \xrightarrow[\rightarrow]{k_{1}} \mathrm{I}$ |
| ---: | :--- |
| Step 2; | $\mathrm{I} \xrightarrow{k_{2}} \mathrm{P}$ |
| Overall reaction: | $\mathrm{A} \xrightarrow{k} \mathrm{P}$ |

Overall reaction:

$$
\mathrm{A} \xrightarrow{k} \mathrm{P}
$$

From the above we can deduce how the concentrations of $\mathrm{A}, \mathrm{I}$, and P will change over time. It is important to consider the relative rates of each step to understand the variation in concentrations of the species participating in the reaction. In any case, the concentration of A will decrease as the reaction proceeds, and the concentration of the product P will increase. But what would be the concentration of the intermediate, I? It is formed in one step and consumed in another. Its concentration must be zero at the start of the reaction, and must be zero when the reaction is complete, but non-zero in between. This is best observed by examining concentration-time curves. Figure 1.26 shows concentration-time curves of these species in three cases.

Figure 1.26 (a) Step 1 faster than Step 2. (b) Step 2 a little faster than Step 1. (c) Step 2 much faster than Step1.

In (a) the first step is somewhat faster than the second step. Initially, as A $\rightarrow$ I occurs, the rate of formation of I is greater than its rate of consumption in Step 2. So, the concentration of I increases over time. Then, as reactant A is depleted and the concentration of I increases, the rate of formation of I decreases and its rate of consumption increases. At this point, the concentration of I starts to decrease. Eventually the concentrations of both A and I drop to near zero as the reaction nears completion. (b) shows a case where Step 2 is somewhat faster than Step 1. In this case, I is consumed more quickly and its concentration does not build up as much as in (a). (c) shows a case where Step 2 is much faster than Step 1. In this case, I is consumed almost instantly as it is formed. The concentration of I never rises to an appreciable level and I may never be concentrated enough to observe in an experiment.

If a case like (c) occurs, it is important to know that the intermediate ever existed or not. Additional experiments can be designed to show that the intermediate was present, even if not directly observed. One of the methods is the addition of another reagent that would react with the postulated intermediate and observing the expected product. Then we can have evidence for the existence of the intermediate.

### 1.10.7 Cases where a pre-equilibrium exists in a mechanism

## Example 1:

Suppose the mechanism for a reaction A $+\mathrm{B} \rightarrow \mathrm{P}$

$$
\mathrm{A} \rightleftharpoons \mathrm{I} ; \text { fast }
$$

$$
\mathrm{I}+\mathrm{B} \rightarrow \mathrm{P}: \text { slow }
$$

This time the slow step is the second step and the intermediate I reaches an equilibrium with the reactants A and B. This mechanism involves a pre-equilibrium, in which an intermediate is in equilibrium with the reactants.

A pre-equilibrium arises when the rates of formation of the intermediate and its decay back into reactants are much faster than its rate of formation of the products.

The rate of the reaction will be governed by the slow step, and so the rate equation of the slow step is: Rate $=k[\mathrm{~B}][\mathrm{I}]$

In the rate law the concentration of the intermediate $I$ is appearing and however, it is known that I is in equilibrium with A . Therefore the equilibrium constant $K_{c}$ for the first step is;

$$
\begin{aligned}
& K_{c}=\frac{[\mathrm{I}]}{[\mathrm{A}]} \\
\therefore & {[\mathrm{I}]=K_{c}[\mathrm{~A}] }
\end{aligned}
$$

Therefore the rate of the reaction is:
Rate $=k[\mathrm{~B}] K_{c}[\mathrm{~A}]=k K_{c}[\mathrm{~A}][\mathrm{B}]$
This can further be modified with the relation between rate constants and equilibrium constant of the reaction. If the rate constants for the forward and backward reactions are $k_{f}$ and $k_{r}$, respectively, we can write;

$$
K_{c}=\frac{k_{f}}{k_{r}}
$$

Finally,

$$
\begin{aligned}
& \quad \therefore \text { Rate }=k \frac{k_{f}}{k_{r}}[\mathrm{~A}][\mathrm{B}] \\
& \text { Rate }=k^{\prime}[\mathrm{A}][\mathrm{B}]
\end{aligned}
$$

The above shows that the rate law is similar to that of an elementary bimolecular reaction.
Consider another example.
Suppose the mechanism for a reaction $\mathrm{A}+\mathrm{B} \rightarrow \mathrm{P}$

$$
\begin{gathered}
\mathrm{A}+\mathrm{B} \rightleftharpoons \mathrm{I} ; \text { fast } \\
\mathrm{I}+\mathrm{A} \rightarrow \mathrm{P}: \text { slow }
\end{gathered}
$$

The overall reaction is;

$$
2 A+B \rightarrow P
$$

The rate of the reaction will be governed by the slow step, so the rate equation of the slow step is :

$$
\text { Rate }=k[\mathrm{~A}][\mathrm{I}]
$$

In the rate law the concentration of the intermediate I is appears. However, it is known that I is in equilibrium with A and B , so the equilibrium constant $K_{c}$ for the first step is;

$$
\begin{aligned}
& \quad K_{c}=\frac{[\mathrm{I}]}{[\mathrm{A}][\mathrm{B}]} \\
& \therefore \quad[\mathrm{I}]=K_{c}[\mathrm{~A}][\mathrm{B}] \\
& \therefore \text { Rate }=k K_{c}[\mathrm{~A}][\mathrm{A}][\mathrm{B}] \\
& \therefore \text { Rate }=k^{\prime}[\mathrm{A}]^{2}[\mathrm{~B}]
\end{aligned}
$$

The rate law obeys the termolecular elementary reaction.

## Example 2:

The gas phase reaction between $\mathrm{H}_{2}(\mathrm{~g})$ and $\mathrm{I}_{2}(\mathrm{~g})$ is one example for the above type of reactions.

$$
\mathrm{H}_{2}(\mathrm{~g})+\mathrm{I}_{2}(\mathrm{~g}) \rightarrow 2 \mathrm{HI}(\mathrm{~g})
$$

This has a fast pre-equilibrium step in which molecular iodine converts to atoms.

$$
\mathrm{I}_{2}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{I}(\mathrm{~g})
$$

Then that atomic iodine reacts with molecular hydrogen to form HI in a slow second step.

$$
\mathrm{H}_{2}(\mathrm{~g})+2 \mathrm{I}(\mathrm{~g}) \rightarrow 2 \mathrm{HI}(\mathrm{~g})
$$

The rate of the reaction is governed by the slow step, so the rate equation of the slow step is:

$$
\text { Rate }=k\left[\mathrm{H}_{2}(\mathrm{~g})\right][\mathrm{I}(\mathrm{~g})]^{2}
$$

In the rate law, the concentration of the intermediate, I appears. However, it is known that I is in equilibrium with $\mathrm{I}_{2}(\mathrm{~g})$. Therefore the equilibrium constant $\boldsymbol{K}_{\boldsymbol{c}}$ for the first step is;

$$
\begin{gathered}
K_{c}=\frac{[\mathrm{I}(\mathrm{~g})]^{2}}{\left[\mathrm{I}_{2}(\mathrm{~g})\right]} \\
\left.\therefore[\mathrm{I}(\mathrm{~g})]^{2}=K_{c} \mathrm{II}_{2}(\mathrm{~g})\right] \\
\therefore \text { Rate }=k K_{c}\left[\mathrm{I}_{2}(\mathrm{~g})\right]\left[\mathrm{H}_{2}(\mathrm{~g})\right] \\
\therefore \text { Rate }=k^{\prime}\left[\mathrm{I}_{2}(\mathrm{~g})\right]\left[\mathrm{H}_{2}(\mathrm{~g})\right]
\end{gathered}
$$

Therefore, the rate of reaction depends on the concentrations of both $\mathrm{I}_{2}(\mathrm{~g})$ and $\mathrm{H}_{2}(\mathrm{~g})$.

## Example 3:

In this example in which the first step of the reaction is a fast and reversible. Consider the oxidation of nitrogen monoxide given below.

$$
2 \mathrm{NO}(g)+\mathrm{O}_{2}(g) \rightarrow 2 \mathrm{NO}_{2}(g)
$$

The observed rate law is

$$
\text { Rate }=k[\mathrm{NO}(\mathrm{~g})]^{2}\left[\mathrm{O}_{2}(\mathrm{~g})\right]
$$

the reaction has the mechanism;

$$
\text { Step 1: } \mathrm{NO}(g)+\mathrm{O}_{2}(g) \rightleftharpoons \mathrm{NO}_{3}(g): \text { fast }
$$

Step 2 : $\mathrm{NO}_{3}(g)+\mathrm{NO}(g) \rightarrow 2 \mathrm{NO}_{2}(g)$ : slow; rate determining step
The sum of the above two steps gives the overall reaction $2 \mathrm{NO}(g)+\mathrm{O}_{2}(g) \rightarrow 2 \mathrm{NO}_{2}(g)$ and both steps are bimolecular.
Rate law for the slow step is;

$$
\text { Rate }=k\left[\mathrm{NO}_{3}(g)\right][\mathrm{NO}(g)]
$$

For the step 1, equilibrium constant is,

$$
\begin{gathered}
K_{c}=\frac{\left[\mathrm{NO}_{3}(\mathrm{~g})\right]}{[\mathrm{NO}(\mathrm{~g})]\left[\mathrm{O}_{2}(\mathrm{~g})\right]} \\
\therefore\left[\mathrm{NO}_{3}(\mathrm{~g})\right]=K_{c}[\mathrm{NO}(\mathrm{~g})]\left[\mathrm{O}_{2}(\mathrm{~g})\right] \\
\therefore \text { Rate }=k K_{c}[\mathrm{NO}(\mathrm{~g})]\left[\mathrm{O}_{2}(\mathrm{~g})\right][\mathrm{NO}] \\
\text { Rate }=k^{\prime}[\mathrm{NO}(\mathrm{~g})]^{2}\left[\mathrm{O}_{2}(\mathrm{~g})\right]
\end{gathered}
$$

This derived rate law is constant with the empirical rate law given earlier. Therefore, the mechanism of the reaction is correct.

### 1.11 Energy profiles of reactions

First, consider an elementary reaction which occurs through a single step A $\rightarrow$ products. As described in earlier sections about the requirements to be satisfied for a chemical reaction to occur when two molecules approach each other, repulsion between their electron clouds continually increase, so they slow down as some of their kinetic energy is converted to potential energy. If they collide, but the energy of the collision is less than the activation energy, the molecules bounce off from each other.

According to Maxwell-Boltzmann distribution, however, in a fraction of collisions in which the molecules are moving fast enough, their kinetic energies push them together with enough force to overcome the repulsions and surmount the activation energy. Usually in this fraction of sufficiently energetic collisions, the molecules are oriented effectively. In those cases, nuclei in one molecule attract electrons in the other, atomic orbitals overlap, electron densities shift, and some bonds lengthen and weaken while others shorten and strengthen. At some point during this smooth transformation, a species with partial bonds exists that is neither a reactant nor a product. This very unstable species, called the transition state (or activated complex) exists only at the instant of highest potential energy. Thus, the activation energy of a reaction is used to reach the transition state. Reaching the transition state does not guarantee that a reaction will proceed to products because a transition state can change in either direction. In this case, if the new bond continues to strengthen, products form; but, if the existing bond becomes stronger again, the transition state reverts to reactants.

A useful way to depict these events is with a reaction energy diagram or energy profile which plots how potential energy changes as the reaction proceeds from reactants to products (the reaction progress or reaction coordinate). The diagram shows the relative energy levels of reactants, products, and transition state, as well as the forward and reverse activation energies and the enthalpy of reaction. Simply the energy profiles can be depicted for single step exothermic and endothermic reactions as shown in Figure 1.27 considering some hypothetical reactions given below.
$\mathrm{AB}+\mathrm{C} \rightarrow \mathrm{A}+\mathrm{BC}: \Delta H<\mathrm{O}$ and $\mathrm{PQ}+\mathrm{R} \rightarrow \mathrm{P}+\mathrm{QR}: \Delta H>\mathrm{O}$.

## G.C.E. (A/L) CHEMISTRY: UNIT 11 Chemical Kinetics

Figure 1.27 Energy profiles for (a) exothermic and (b) endothermic reactions going through a single transition state.

Figure 1.27(a) shows that, overall, the reaction is exothermic. The products have lower energy than the reactants, so energy is released when the reaction happens. It also shows that the molecules have to possess enough energy (activation energy) to get the reactants over the "activation energy barrier".

For an endothermic reaction, a simple energy profile is shown in Figure 1.27(b).
For example, following two reactions occur through a single step with a single transition state. The reaction; $\mathrm{NO}(\mathrm{g})+\mathrm{O}_{3}(\mathrm{~g}) \rightarrow \mathrm{NO}_{2}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g})$ is exothermic while the reaction $2 \mathrm{NOCl}(\mathrm{g}) \rightarrow 2 \mathrm{NO}(\mathrm{g})+\mathrm{Cl}_{2}(\mathrm{~g})$ is endorthermic. Their transition states are also shown along with the potential energy in Figure 1.28.

Figure 1.28 Energy profiles for two gas-phase reactions of (a) exothermic and (b) endothermic nature. In each case, the structure of the transition state is predicted from the orientations of the reactant atoms that must become bonded in the product.

## G.C.E. (A/L) CHEMISTRY: UNIT 11 Chemical Kinetics

As another example, the reaction below shows a reaction in which a bromine atom of bromoethane is being replaced by an OH group to produce ethanol.

$$
\mathrm{CH}_{3} \mathrm{Br}(\mathrm{aq})+\mathrm{OH}^{-}(\mathrm{aq}) \rightarrow \mathrm{CH}_{3} \mathrm{OH}(\mathrm{aq})+\mathrm{Br}^{-}(\mathrm{aq})
$$

In the reaction one of the lone pairs of electrons on the negatively charged oxygen in the $\mathrm{OH}^{-}$ion is attracted to the carbon atom with the bromine attached.

As the bromine is more electronegative than carbon, and so the electron pair in the $\mathrm{C}-\mathrm{Br}$ bond is slightly closer to the bromine. The carbon atom becomes slightly positively charged and the bromine slightly negative. As the hydroxide ion approaches the slightly positive carbon, a new bond starts to be set up between the oxygen and the carbon. At the same time, the bond between the carbon and bromine starts to break as the electrons in the bond are repelled towards the bromine.

At some point, the process is exactly half complete. The carbon atom now has the oxygen half-attached, the bromine half-attached, with three other groups still there and then the process undergo completion. The structure in which the bonds are half-made and halfbroken is the transition state, and is at the maximum potential energy.

It has to be noted that the transition state is entirely unstable. Any tiny change in either direction will send it either forward to make the products or back to the reactants again. There is no anything special about a transition state except that it has this maximum energy.

Figure 1.29 Energy profile for the reaction $\mathrm{CH}_{3} \mathrm{Br}+\mathrm{OH}^{-} \rightarrow \mathrm{CH}_{3} \mathrm{OH}+\mathrm{Br}^{-}$

## G.C.E. (A/L) CHEMISTRY: UNIT 11 Chemical Kinetics

## Example 1.15

The reaction, $\mathrm{O}_{3}(\mathrm{~g})+\mathrm{O}(\mathrm{g}) \rightarrow 2 \mathrm{O}_{2}(\mathrm{~g})$ has the activation energy of $19 \mathrm{~kJ} \mathrm{~mol}^{-1}$ for the forward reaction and the $\Delta H$ for the reaction is $-392 \mathrm{~kJ} \mathrm{~mol}^{-1}$. Draw an energy profile for the reaction with approximate relative positions of the species. Estimate the activation energy for the backward reaction.

## Answer

Figure 1.30 Energy profile for the reaction $\mathrm{O}_{3}(\mathrm{~g})+\mathrm{O}(\mathrm{g}) \rightarrow 2 \mathrm{O}_{2}(\mathrm{~g})$.

Calculation of the activation energy of the backward reaction is indicated in the figure and the postulated structure of the transition state is also drawn.

## Energy profiles for reactions which go via an intermediate

In this case, consider the following reaction which goes through an intermediate.

$$
\left(\mathrm{CH}_{3}\right)_{3} \mathrm{CBr}+\mathrm{OH}^{-} \rightarrow\left(\mathrm{CH}_{3}\right)_{3} \mathrm{COH}+\mathrm{Br}^{-}
$$

In the overall reaction the bromine atom is replaced by an OH group.
As mentioned earlier the reaction occurs via two steps as follows.

$$
\begin{aligned}
& \left(\mathrm{CH}_{3}\right)_{3} \mathrm{CBr} \rightleftharpoons\left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}^{+}+: \mathrm{Br}^{-}: \text {slow } \\
& \left(\mathrm{CH}_{3}\right)_{3} \mathrm{C}^{+}+: \mathrm{OH}^{-} \rightleftharpoons\left(\mathrm{CH}_{3}\right)_{3} \mathrm{COH}: \text { fast }
\end{aligned}
$$

The main difference in this case is that the positively charged ion can actually be detected in the mixture. It is very unstable, short-lived and soon reacts with a hydroxide ion (or picks up its bromide ion again). But, it does have a real presence in the system. The stability (however temporary and slight) of the intermediate is shown by the fact that there are small activation barriers to its conversion either into the products or back into the reactants again.

Notice that the barrier on the product side of the intermediate is lower than that on the reactant side meaning the fast second step as shown in Figure 1.30(a). That means, there is a greater chance of it to find the extra bit of energy to convert into products. It would need a greater amount of energy to convert back to the reactants again. The " $\mathrm{TS}_{1}$ " and " $\mathrm{TS}_{2}$ " both represent transition states between the intermediate and either the reactants or the products. During either conversion, there will be some arrangement of the atoms which causes an energy maximum.

Figure 1.31 Energy profiles for two reactions, each of which has a two-step mechanism. (a) The reaction starts with a slow step, and (b) The reaction starts with a fast step. Both overall reactions are exothermic. Note these key points: Each step in the mechanism has its own peak with the transition state at the top. The intermediates are reactive, unstable species, so they are higher in energy than the reactants or product. The slow (rate-determining) step (step 1 in (a) and step 2 in (b) has a larger $\mathrm{E}_{\mathrm{a}}$ than the other step.

## G.C.E. (A/L) CHEMISTRY: UNIT 12 Chemical Equilibrium

## Introduction

In the previous units, we have analyzed key questions about chemical reactions: What happens, how fast and by what mechanism does it happen? It is very much needed to know that "to what extent does it happen?" The stoichiometry of the balanced chemical equation, and the kinetics of the reaction explain the answers to first two questions respectively, and in this unit we look for the answer to the question, how far does a reaction proceed toward completion before it reaches a state of equilibrium a state in which the concentrations of reactants and products no longer change. This state is reached when the concentrations of reactants and products remain constant over time. Equilibrium can be established for both physical processes and chemical reactions. The reaction may be fast or slow depending on the experimental conditions and the nature of the reactants. When the reactants in a closed vessel at a particular temperature react to give products, the concentrations of the reactants keep on decreasing, while those of products keep on increasing for some time after which there is no change in the concentrations of either the reactants or products. This stage of the system is the dynamic equilibrium and the rates of the forward and reverse reactions become equal. At this dynamic equilibrium stage it is recognized that there is no change in macroscopic properties such as pressure, colour of the solution, or concentration of the solution at a constant temperature. However, at the atomic level, atoms, ions, and/or molecules are in constant reaction. When a system is a gas partial pressures are used to represent the amounts of substances present in the equilibrium condition.

The extent of a reaction in equilibrium varies with the experimental conditions such as concentrations/pressures of reactants, temperature, etc. Some important aspects of equilibrium involving physical and chemical processes are dealt in this unit along with the equilibrium involving ions in aqueous solutions which is called ionic equilibrium. Finally, the equilibrium in gas-liquid systems will be discussed.

### 2.1 The concept of equilibrium

Consider a chemical reaction between reactants $\mathbf{A}$ and $\mathbf{B}$ to form products $\mathbf{C}$ and $\mathbf{D}$. After allowing sufficient period of time for the reaction, upon analyses, when $\mathbf{A}$ and $\mathbf{B}$ are absent in the reaction mixture, the reaction is understood to be completed and only the presence of $\mathbf{C}$ and $\mathbf{D}$ will be detected. That reaction can be written as,

$$
\begin{equation*}
\mathrm{A}+\mathrm{B} \rightarrow \mathrm{C}+\mathrm{D} \tag{1}
\end{equation*}
$$

In this reaction, the reverse reaction to form back the reactants never occurs even when the reaction vessel is a closed one. Reactions which go to completion and never proceed in the reverse direction are called irreversible reactions.

However, even after allowing sufficient period of time for reaction, when the presence of $\mathbf{A}$ and $\mathbf{B}$ are always detected along with $\mathbf{C}$ and $\mathbf{D}$, then such reactions are understood to be never completed. i.e. Initially the reaction proceeds to form $\mathbf{C}$ and $\mathbf{D}$ until a certain period of time and with further increase in the reaction time, $\mathbf{C}$ and $\mathbf{D}$ molecules start to
produce back $\mathbf{A}$ and $\mathbf{B}$ and in such a way, the reaction mixture always contains $\mathbf{A}, \mathbf{B}, \mathbf{C}$ and $\mathbf{D}$ for any length of time until external factors like temperature, pressure, catalyst etc. are applied. Reactions which never proceed to completion in both forward and backward direction are called equilibrium reactions (or reversible reactions) and the system is said be reached an equilibrium state. A mixture of reactants and products in the equilibrium state is called an equilibrium mixture. And the chemical equation of such reactions are represented as,

$$
\begin{equation*}
\mathrm{A}+\mathrm{B} \rightleftharpoons \mathrm{C}+\mathrm{D} \tag{2}
\end{equation*}
$$

To indicate that the reaction can proceed in both forward and reverse directions, we write the balanced equation with two arrows, $\rightleftharpoons$, one pointing from reactants to products and the other pointing from products to reactants.

These two cases of completion of reaction and reaching a reaction to an equilibrium state can be represented graphically as shown in the Figure 2.1 below.

Figure 2.1 Change in concentrations of reactants and products over the time (a) for an irreversible and (b) equilibrium reactions at a given temperature

At the start of a reversible reaction, first reaction proceeds in the forward direction to form products. Once the product concentration increases with time they begin to react back to form reactant molecules. Therefore, the chemical equilibrium may be defined as the state of a reversible reaction when the two opposing reactions occur at the same rate and the concentration of reactants and products do not change with time. The true equilibrium of a reaction can be attained from both sides proving that the chemical equilibrium is a dynamic process. This nature can be illustrated for the reaction (2) with the help of Figure 2.2. It has to be noted that the equilibrium concentrations of reactants are different from their initial concentrations.

Figure 2.2 When the two rates become equal at a given temperature, an equilibrium state is attained with equalizing the rates of forward and backward reactions and there are no further changes in concentrations.

When a reversible reaction attains equilibrium it appears that the concentrations of individual reactants and that of the products remain constant with time. Actually, the reactant molecules are always reacting to form the product molecules. When the product molecules are able to react with themselves under the same experimental condition to form the same amount of reactants simultaneously (at the same time) in an equal rate of the forward reaction, then the process is a ceaseless phenomenon. Thus chemical equilibrium is dynamic when the forward and reverse reactions take place endlessly and simultaneously with equal rates. Therefore a chemical equilibrium is called a dynamic equilibrium. Hence, we can understand that;
(i) When a chemical equilibrium is established in a closed container at constant temperature, the concentrations of various species like reactants and products remain unchanged.
(ii) Equilibrium can be initiated from either side. The state of equilibrium of a reversible reaction can be arrived at whether we start from reactants or products.
(iii) Equilibrium cannot be attained in an open container. Only in a closed container, a reaction can be considered to attain equilibrium since no part of reactants or products should escape out. In an open container, gaseous reactants or products may escape so that no possibility of attaining equilibrium exists. Equilibrium can be attained when all the reactants and products are in contact with each other.

The phenomenon discussed above can be understood by the following example. Consider a simple system that contains only one reactant and one product, the reversible dissociation of dinitrogen tetroxide $\left(\mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g})\right)$ to nitrogen dioxide $\left(\mathrm{NO}_{2}(\mathrm{~g})\right) . \mathrm{NO}_{2}(\mathrm{~g})$ is responsible for the brown color we associate with smog. In a sealed vessel containing $\mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g})$, the red-brown colour of $\mathrm{NO}_{2}(\mathrm{~g})$ appears. Therefore the reaction can be followed
visually because the product $\left(\mathrm{NO}_{2}(\mathrm{~g})\right)$ is coloured, whereas the reactant $\left(\mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g})\right)$ is colourless.

$$
\begin{equation*}
\mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{NO}_{2(\mathrm{~g})} \tag{3}
\end{equation*}
$$

This system can be used to understand the reversible nature of a reaction which attains equilibrium in three ways.
(i) When gaseous $\mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g})$ is injected into an evacuated flask brown colour appears immediately, indicating the formation of $\mathrm{NO}_{2}(\mathrm{~g})$ molecules. The colour intensifies with the time as the dissociation of $\mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g})$ continues until eventually equilibrium is reached and remains at a constant intensity. At this point, the concentrations of both $\mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g})$ and $\mathrm{NO}_{2}(\mathrm{~g})$ remain constant.
(ii) We can also bring about an equilibrium state by starting with pure $\mathrm{NO}_{2}(\mathrm{~g})$. As some of the $\mathrm{NO}_{2}(\mathrm{~g})$ molecules combine to form $\mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g})$, the colour fades and remains at constant intensity once the equilibrium is attained.
(iii) Another way to create this equilibrium state is to start with a mixture of $\mathrm{NO}_{2}(\mathrm{~g})$ and $\mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g})$ and monitor the system until the color stops changing. The important thing to keep in mind is that at equilibrium, the conversions of $\mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g})$ to $\mathrm{NO}_{2}(\mathrm{~g})$ and $\mathrm{NO}_{2}(\mathrm{~g})$ to $\mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g})$ are still going on. We do not see a colour change because the two rates are equal, i.e. the removal of $\mathrm{NO}_{2}(\mathrm{~g})$ molecules takes place as fast as the production of $\mathrm{NO}_{2}(\mathrm{~g})$ molecules, and $\mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g})$ molecules are formed as quickly as they dissociate. Figure 2.3 summarizes these three situations.

Figure $2.3 \quad \mathrm{~N}_{2} \mathrm{O}_{4}(\mathrm{~g}) \rightleftharpoons \mathrm{NO}_{2}(\mathrm{~g})$ equilibrium system: (a) Initially, the system contains gaseous $\mathrm{NO}_{2}(\mathrm{~g})$ and no gaseous $\mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g})$. The concentration of $\mathrm{NO}_{2}(\mathrm{~g})$ decreases with time as the concentration of $\mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g})$ increases. (b) Initially the system contains gaseous $\mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g})$ and no gaseous $\mathrm{NO}_{2}(\mathrm{~g})$. The concentration of $\mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g})$ decreases with time as the concentration of $\mathrm{NO}_{2}(\mathrm{~g})$ increases. (c) Initially a mixture of $\mathrm{NO}_{2}(\mathrm{~g})$ and $\mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g})$ is present. Note that even though equilibrium is reached in all cases, the equilibrium concentrations of $\mathrm{NO}_{2}(\mathrm{~g})$ and $\mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g})$ are not the same. (d) Rates of forward and backward reactions in the mixture described in (c). Note also that even though the values of concentrations are not marked variation in concentrations are in parallel with the stoichiometry of the reaction.

When there is a change in the state of occurrence of matter, then a physical transformation is said to have occurred. The equilibrium concepts are also applicable to physical state transformations of matter and some examples are discussed below.

### 2.1.1 Equilibrium in physical processes

The characteristics of a system at equilibrium are better understood if we examine some physical processes. The most familiar examples are phase transformation processes, e.g.: solid $\rightleftharpoons$ liquid, liquid $\rightleftharpoons$ gas, solid $\rightleftharpoons$ gas etc.

## Solid-liquid equilibrium

Here, the solid and the liquid forms of a substance co-exist at characteristic temperature and pressure. At 1 atm and at the melting point of a substance, there is a solid-liquid equilibrium existing. For example, the solid-liquid equilibrium of water at $273 \mathrm{~K}\left(0^{\circ} \mathrm{C}\right)$,

$$
\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{H}_{2} \mathrm{O}(\mathrm{~s})
$$

occurs at atmospheric pressure ( $1 \mathrm{~atm}, 101325 \mathrm{~Pa}$ ). Here, both the liquid and ice exist together. We observe that the mass of ice and water do not change with time and the temperature remains constant. However, the equilibrium is not static. At the boundary between liquid and solid, molecules from the liquid water collide against ice and adhere to it and some molecules of ice escape into liquid phase. There is no change of mass of ice and water, as the rates of transfer of molecules from ice into water and of reverse transfer from water into ice are equal at atmospheric pressure and 273 K . It is obvious that ice and water are in equilibrium only at a particular temperature and pressure. "For any pure substance at atmospheric pressure, the temperature at which the solid and liquid phases are at equilibrium is called the normal melting point or normal freezing point of the substance". In this example, we can see that the system is in dynamic equilibrium and at the melting point of ice or freezing point of water, the rate of melting of ice equals to the rate of freezing of water so that the amount of ice and water remains constant. It has to be noted that with change in pressure, the temperature at which this equilibrium onsets changes.

## Liquid-vapour equilibrium

Here, the solid and the vapour forms of a substance co-exist at a characteristic temperature and pressure in a closed system. At 1 atm and at the boiling point of a substance, there is a liquid- vapour equilibrium existing. For example, the liquid- vapour equilibrium of water at $373 \mathrm{~K}\left(100^{\circ} \mathrm{C}\right)$,

$$
\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{H}_{2} \mathrm{O}(\mathrm{~g})
$$

occurs at atmospheric pressure. Here, both the liquid and vapour exist together. This can be demonstrated by a simple experiment by putting a watch glass containing certain amount of water in previously evacuated and dried box connected with a barometer (pressure-meter) at $100^{\circ} \mathrm{C}$. It will be observed that the mercury level in the right limb of
the manometer slowly increases and finally attains a constant value, that is, the pressure inside the box increases and reaches a constant value. Also the volume of water in the watch glass decreases. Initially there was no water vapour (or very less) inside the box. As water evaporated the pressure in the box increased due to addition of water molecules into the gaseous phase inside the box. The rate of evaporation is constant. However, the rate of increase in pressure decreases with time due to condensation of vapour into water. Finally it leads to an equilibrium condition when there is no net evaporation. This implies that the number of water molecules from the gaseous state into the liquid state also increases till the equilibrium is attained at which the rate of evaporation equals the rate of condensation.

At equilibrium the pressure exerted by the water molecules at a given temperature remains constant and is called the "equilibrium vapour pressure" of water (or just vapour pressure of water); vapour pressure of water increases with temperature.

Here "the vapour and the liquid forms of a substance exist simultaneously at 1 atm pressure and at a characteristic temperature called the boiling point". For example, at 1 $\operatorname{atm}$ pressure, $100{ }^{\circ} \mathrm{C}$ is the boiling point of water, and both liquid water and water vapour (steam) exist simultaneously, provided the vapour does not escape.

## Solid - vapour equilibrium

If we place solid iodine in a closed vessel, after sometime the vessel gets filled up with violet vapour and the intensity of colour increases with time. After a certain time, the intensity of colour becomes constant and at this stage equilibrium is attained. Hence solid iodine sublimes to give iodine vapour and the iodine vapour condenses to give solid iodine. The equilibrium can be represented as, $\mathrm{I}_{2}(\mathrm{~s}) \rightleftharpoons \mathrm{I}_{2}(\mathrm{~g})$

## Solid-solid equilibrium

When a substance existing in a particular crystalline solid transforms to another crystalline form retaining its solid nature at a characteristic temperature called the transition temperature with both the solid forms coexisting at 1 atm pressure, it is said to be in solid-solid equilibrium. For example, solid sulphur exhibits equilibrium with rhombic to monoclinic forms at its transition temperature.

$$
\mathrm{S}(\text { rhombic }) \rightleftharpoons \mathrm{S}(\text { monoclinic })
$$

### 2.1.2 Equilibrium in chemical processes

## Homogeneous equilibrium

Chemical equilibrium exists in two types, homogeneous and heterogeneous. In a chemical reaction existing in equilibrium, if all the reactants and products are present in the same phase, a homogeneous equilibrium is said to have occurred. For example,

$$
\mathrm{N}_{2}(\mathrm{~g})+3 \mathrm{H}_{2}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{NH}_{3}(\mathrm{~g})
$$

Here all the reactants and products exist in the gaseous state. This is an example of a gasphase equilibrium.

A chemical equilibrium in which all the reactants and products are in the liquid phase referred to as liquid equilibrium. For example,

$$
\mathrm{CH}_{3} \mathrm{COOH}(\mathrm{l})+\mathrm{C}_{2} \mathrm{H}_{5} \mathrm{OH}(\mathrm{l}) \rightleftharpoons \mathrm{CH}_{3} \mathrm{COOC}_{2} \mathrm{H}_{5}(\mathrm{l})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

Both gas phase and liquid phase equilibria are collectively called homogeneous equilibria.

## Heterogeneous equilibrium

In a chemical equilibrium, if the reactant and product species are in different phases then heterogeneous equilibrium is said to have occurred.

$$
\begin{gathered}
\mathrm{CaCO}_{3}(\mathrm{~s}) \rightleftharpoons \mathrm{CaO}(\mathrm{~s})+\mathrm{CO}_{2}(\mathrm{~g}) \\
3 \mathrm{Fe}(\mathrm{~s})+4 \mathrm{H}_{2} \mathrm{O}(\mathrm{~g}) \rightleftharpoons \mathrm{Fe}_{3} \mathrm{O}_{4}(\mathrm{~s})+4 \mathrm{H}_{2}(\mathrm{~g})
\end{gathered}
$$

Here, when the reaction is carried out in a closed vessel, the equilibrium state is established.

### 2.1.3 Law of chemical equilibrium and equilibrium constant

It is important to know the relationship between the concentrations of reactants and products in an equilibrium mixture, how to determine equilibrium concentrations from initial concentrations and what factors can be exploited to alter the composition of an equilibrium mixture? Two Norwegian Chemists, Guldberg and Waage, studied experimentally a large number of equilibrium (reversible) reactions. In 1864, they postulated a generalization called the law of mass action. It states that: "the rate of a chemical reaction is proportional to the active masses of the reactants". By the term `active mass', it is meant the molar concentration i.e., $\mathrm{mol} \mathrm{dm}^{-3}$. At a fixed temperature the rate of a reaction is determined by the number of collisions between the reactant molecules present in a unit volume and hence its concentration, which is generally referred to as the active mass.

Consider a reaction,

$$
\mathrm{A}+\mathrm{B} \underset{k_{r}}{\stackrel{k_{f}}{\rightleftharpoons}} \mathrm{C}+\mathrm{D}
$$

According to the law of mass action;
Rate of forward reaction: $R_{f}=k_{f}[\mathrm{~A}][\mathrm{B}]$
Rate of backward reaction: $R_{r}=k_{r}[\mathrm{C}][\mathrm{D}]$
$[\mathrm{A}],[\mathrm{B}],[\mathrm{C}]$ and $[\mathrm{D}]$ are the molar concentrations of $\mathrm{A}, \mathrm{B}, \mathrm{C}$ and D at equilibrium, respectively.
$k_{f}$ and $k_{r}$ are the rate constants of forward and backward reactions, respectively.
At equilibrium,

$$
R_{f}=R_{r}
$$

Therefore we can write, $\quad k_{f}[\mathrm{~A}][\mathrm{B}]=k_{r}[\mathrm{C}][\mathrm{D}]$
And

$$
\frac{k_{f}}{k_{r}}=\frac{[C][D]}{[A][B]}
$$

At any specific temperature $\frac{k_{f}}{k_{r}}$ is a constant since both $k_{f}$ and $k_{r}$ are constants. The ratio $\frac{k_{f}}{k_{r}}$ is called equilibrium constant and is represented by the symbol $\boldsymbol{K}_{c}$. The subscript ${ }^{\text {c }}$ ' indicates that the value is in terms of concentration of reactants and products. The equation (I) may be written as

$$
K_{C}=\frac{[C][D]}{[A][B]}
$$

i.e. for a reversible reaction in equilibrium at constant temperature, a certain ratio of reactant and product concentrations has a constant value, $\boldsymbol{K}_{\boldsymbol{c}}$ (the equilibrium constant).

### 2.1.4 Equilibrium law and equilibrium constant expression for a reaction

For example in the study of analysis of experimental data by changing the initial concentrations of $\mathrm{NO}_{2(\mathrm{~g})}$ and $\mathrm{N}_{2} \mathrm{O}_{4(\mathrm{~g})}$ in a $\mathrm{N}_{2} \mathrm{O}_{4(\mathrm{~g})} \rightleftharpoons 2 \mathrm{NO}_{2(\mathrm{~g})}$ system at $25^{\circ} \mathrm{C}$ some interesting pattern is seen: Analysis of the equilibrium concentration data shows that although the ratio $\left[\mathrm{NO}_{2(\mathrm{~g})}\right] /\left[\mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g})\right]$ gives random values, the ratio $\left[\mathrm{NO}_{2}(\mathrm{~g})\right]^{2} /\left[\mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g})\right]$ gives a nearly constant value. i.e.

$$
K_{\mathrm{c}}=\frac{\left[\mathrm{NO}_{2}(\mathrm{~g})\right]^{2}}{\left[\mathrm{~N}_{2} \mathrm{O}_{4}(\mathrm{~g})\right]}
$$

is a constant at a given temperature.
Likewise, similar kind of results was observed for the $\mathrm{H}_{2}(\mathrm{~g})+\mathrm{I}_{2}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{HI}(\mathrm{g})$ reaction giving the ratio $[\mathrm{HI}]^{2} /\left[\mathrm{H}_{2}\right]\left[\mathrm{I}_{2}\right]$ as a constant. With this type of findings in many equilibrium systems at given temperature, we can derive a generalized form for the equilibrium expression of a reaction:

$$
\mathrm{aA}+\mathrm{bB} \rightleftharpoons \mathrm{cC}+\mathrm{dD}
$$

where $a, b, c$, and $d$ are the stoichiometric coefficients for the reacting species $A, B, C$, and D ,

$$
K_{\mathrm{c}}=\frac{[\mathrm{C}]^{\mathrm{c}}[\mathrm{D}]^{\mathrm{d}}}{[\mathrm{~A}]^{\mathrm{a}}[\mathrm{~B}]^{\mathrm{b}}}
$$

where $\boldsymbol{K}_{\mathbf{c}}$ is the equilibrium constant. The general definition of the equilibrium constant may thus be stated as:

The product of the equilibrium concentrations of the products divided by the product of the equilibrium concentrations of the reactants, with each concentration term raised to a power equal to the coefficient of the substance in the balanced equation.

For example, consider the equilibrium constant expression for the reaction,

$$
\begin{gathered}
\mathrm{N}_{2}(\mathrm{~g})+3 \mathrm{H}_{2}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{NH}_{3}(\mathrm{~g}) \\
K_{\mathrm{c}}=\frac{\left[\mathrm{NH}_{3(\mathrm{~g})}\right]^{2}}{\left[\mathrm{~N}_{2(\mathrm{~g})}\right]\left[\mathrm{H}_{2(\mathrm{~g})}\right]^{3}}
\end{gathered}
$$

If we write the chemical equation in the reverse direction, the new equilibrium constant expression is the reciprocal of the original expression and the new equilibrium constant, is the reciprocal of the original equilibrium constant. (The prime distinguishes $K_{\mathrm{c}}^{\prime}$ from $K_{\text {c. }}$ ). i.e.

$$
K_{\mathrm{c}}^{\prime}=\frac{\left[\mathrm{N}_{2(\mathrm{~g})}\right]\left[\mathrm{H}_{2(\mathrm{~g})}\right]^{3}}{\left[\mathrm{NH}_{3(\mathrm{~g})}\right]^{2}}=\frac{1}{K_{\mathrm{c}}}
$$

Because the equilibrium constants $K_{\mathrm{c}}$ and $K_{\mathrm{c}}$ have different numerical values, it is important to specify the form of the balanced chemical equation when quoting the value of an equilibrium constant. Further, it has to be noted that the physical states of the species appearing in the equilibrium constant expressions must be indicated for each as shown above.

## Example 2.1

The following concentrations were measured for an equilibrium mixture of $\mathrm{N}_{2}(\mathrm{~g})+3 \mathrm{H}_{2(\mathrm{~g})} \rightleftharpoons 2 \mathrm{NH}_{3}(\mathrm{~g})$ at $500 \mathrm{~K}:\left[\mathrm{N}_{2}\right]=3.0 \times 10^{-2} \mathrm{~mol} \mathrm{dm}^{-3}$, $\left[\mathrm{H}_{2}\right]=4.0 \times 10^{-2} \mathrm{~mol} \mathrm{dm}^{-3}$ and $\left[\mathrm{NH}_{3}\right]=2 \times 10^{-3} \mathrm{~mol} \mathrm{dm}^{-3}$. Calculate the equilibrium constants for both forward and reverse reactions at 500 K .

## Answer

$\mathrm{N}_{2}(\mathrm{~g})+3 \mathrm{H}_{2}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{NH}_{3}(\mathrm{~g})$

$$
K_{\mathrm{c}}=\frac{\left[\mathrm{NH}_{3(\mathrm{~g})}\right]^{2}}{\left[\mathrm{~N}_{2(\mathrm{~g})}\right]\left[\mathrm{H}_{2(\mathrm{~g})}\right]^{3}}
$$

$$
K_{\mathrm{c}}=\frac{\left(2 \times 10^{-3}\right)^{2}\left(\mathrm{~mol} \mathrm{dm}^{-3}\right)^{2}}{\left(3 \times 10^{-2}\right)\left(4 \times 10^{-2}\right)^{3}\left(\mathrm{~mol} \mathrm{dm}^{-3}\right)^{4}}=2.083 \mathrm{~mol}^{-2} \mathrm{dm}^{6}
$$

$$
K_{\mathrm{c}}^{\prime}=\frac{\left[\mathrm{N}_{2(\mathrm{~g})}\right]\left[\mathrm{H}_{2(\mathrm{~g})}\right]^{3}}{\left[\mathrm{NH}_{3(\mathrm{~g})}\right]^{2}}=\frac{\left(3 \times 10^{-2}\right)\left(4 \times 10^{-2}\right)^{3}\left(\mathrm{~mol} \mathrm{dm}^{-3}\right)^{4}}{\left(2 \times 10^{-3}\right)^{2}\left(\mathrm{~mol} \mathrm{dm}^{-3}\right)^{2}}
$$

$$
=0.48 \mathrm{~mol}^{2} \mathrm{dm}^{-6}
$$

or
$K_{\mathrm{c}}^{\prime}=\frac{1}{K_{c}}=\frac{1}{2.083 \mathrm{~mol}^{-2} \mathrm{dm}^{6}}=0.48 \mathrm{~mol}^{2} \mathrm{dm}^{-6}$
Note: See the change in magnitude as well as the units when the equilibrium constant is defined in two opposite directions in the reaction.The equilibrium constant for a reaction written in reverse is the inverse of the equilibrium constant for the reaction as written originally.

## G.C.E. (A/L) CHEMISTRY: UNIT 12 Chemical Equilibrium

### 2.1.5 Extent of reaction

If $\boldsymbol{K}$ (either $\boldsymbol{K}_{\mathbf{c}}$ or $\boldsymbol{K}_{\mathbf{p}}$ which pertains to the gas phase reactions) is much greater than 1 (that is, $K \ggg 1$ ), the equilibrium will lie to the right and favours the products. That is concentration of products is higher than that of reactants. Conversely, if the equilibrium constant is much smaller than 1 (that is, $K \lll 1$ ), the equilibrium will lie to the left and favours the reactants, i.e. concentration of reactants is higher than that of products. Many reactions have equilibrium constants between 1000 and $0.001\left(10^{3} \geq K \geq 10^{-3}\right)$, indicating they are neither very large nor very small. At equilibrium, these systems tend to contain significant amounts of both products and reactants, indicating that there is not a strong tendency to form either products from reactants or reactants from products.

Figure 2.4 Representation of the extent and equilibrium position of a reaction with respect to the magnitude of equilibrium constant, $\boldsymbol{K}$

Figure 2.4 summarizes the relationship between the magnitude of $K$ and the relative concentrations of reactants and products at equilibrium for a general reaction, written as reactants $\rightleftharpoons$ products. Because there is a direct relationship between the kinetics of a reaction and the equilibrium concentrations of products and reactants when $k_{\mathrm{f}} \gg k_{\mathrm{r}}, \boldsymbol{K}$ is a large number, and the concentration of products at equilibrium predominate. This corresponds to an essentially irreversible reaction. Conversely, when $k_{\mathrm{f}} \ll k_{\mathrm{r}}, \boldsymbol{K}$ is a very small number, and the reaction produces almost no products as written. Systems with $k_{\mathrm{f}}$ $\approx k_{\mathrm{r}}$ have significant concentrations of both reactants and products at equilibrium. i.e.

- If, $\boldsymbol{K}_{\mathbf{c}}>\mathbf{1 0}^{\mathbf{3}}$, products predominate over reactants. If it is very large, the reaction proceeds nearly to completion.
- If, $\boldsymbol{K}_{\mathbf{c}}<\mathbf{1 0}^{\mathbf{3}}$, reactants predominate over products. If it is very small, the reaction proceeds hardly at all.
- If, $1 \mathbf{0}^{\mathbf{3}} \geq K_{\mathbf{c}} \geq \mathbf{1 0}^{\mathbf{- 3}}$, appreciable concentrations of both reactants and products are present.

Figure 2.5 Representation of a spontaneous reaction towards minimum Gibbs function at equilibrium at given temperature and pressure. As the reaction proceeds the slope of the Gibbs function changes. Equilibrium point corresponds to the zero slope.

In addition to the simple description used in Figure 2.4 to understand the position of equilibrium, this equilibrium concept can further be understood by the knowledge of thermochemistry described in unit 05 to explain the spontaneity of reactions. In Figure 2.5 , curve (a) shows that the position of equilibrium lies close to products indicating that the reaction goes to completion where Gibbs energy difference $(\Delta G)_{\mathrm{T}, \mathrm{P}}<0$. The curve (b) represents the state of equilibrium consisting of significant amounts of both reactants and products in the mixture where $(\Delta G)_{\mathrm{T}, \mathrm{P}}=0$. In curve (c) we can see that the position of equilibrium lies close to the reactants where $(\Delta G)_{T, P}>0$, or the reaction is nonspontaneous.

> Note: Here $(\Delta G)_{T, P}$ means the value of free energy change per change in number of moles $\left((\Delta G)_{T, P} / \Delta n\right)$. However, for a given reaction the use of $(\Delta G)_{T, P}=\Delta H-T \Delta S$ gives the standard free energy change of the complete reaction (i.e $\Delta G_{r}{ }^{\circ}$ ). In general, $\Delta G_{r}$ of a given reaction at a given temperature is given by; $\Delta G_{r}=\Delta G_{r}{ }^{\circ}+R T \ln Q$, and we know that at equilibrium, $\Delta G_{r}=0$ indicating that any reaction has its own (characteristic) $\Delta G_{r}{ }^{o}$ value. In other words, for a reaction at a given temperature, $\Delta G_{r}{ }^{o} \neq 0$, or $\Delta G_{r}{ }^{o}=-R T \ln K$. (This is just for the clarification and the equation here is not tested in G.C.E (A/L) examination)

The description of Figure 2.5 can also be represented by the following three diagrams in Figure 2.6 for understanding better about the Gibbs energy changes in a spontaneous chemical reaction, a reaction that goes to completion and a reaction that never proceeds to products.

Figure 2.6 Details of Figure 2.5 (a) Variation of Gibbs free energy with composition for a reaction with spontaneous tendency. (b) A reaction which goes to a completion in which the equilibrium point lies very close to products $(K>1)$ and $(c)$ A reaction which never reaches completion or a reaction which has no tendency to form products in which the equilibrium point lies very close to reactants ( $K \ll 1$ ).

From the Figure 2.6 we can note that;
The equilibrium position, or how close to products or reactants the reaction will go is defined by the magnetude and sign of $\Delta G_{r}^{\ominus}$.
$\Delta G_{r}^{\theta}<0$ : products are favoured.
$\Delta G_{r}^{\ominus} \approx 0:$ neither reactants nor products are favoured and the system is at equilibrium.
$\Delta G_{r}^{\ominus}>0$ : reactants are favoured.

### 2.1.6 Different forms of writing equilibrium constant expression

Writing an equation in different but chemically equivalent forms also causes both the equilibrium constant expression and the magnitude of the equilibrium constant to be different. For example, when the equation for the reaction $2 \mathrm{NO}_{2}(\mathrm{~g}) \rightleftharpoons \mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g})$ with the equilibrium constant K is written as $\mathrm{NO}_{2} \rightleftharpoons 1 / 2 \mathrm{~N}_{2} \mathrm{O}_{4}$, the equilibrium constant $K^{\prime \prime}$; can be written as follows.

$$
\begin{gathered}
K=\frac{\left[\mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g})\right]}{\left[\mathrm{NO}_{2}(\mathrm{~g})\right]^{2}} \\
K^{\prime \prime}=\frac{\left[\mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g})\right]^{1 / 2}}{\left[\mathrm{NO}_{2}(\mathrm{~g})\right]}
\end{gathered}
$$

We can see that the $K^{\prime \prime}$ and K has the relation, $\boldsymbol{K}^{\prime \prime}=(\boldsymbol{K})^{1 / 2}$ and according to the law of mass action, each concentration term in the equilibrium constant expression is raised to a power equal to its stoichiometric coefficient. Thus if you double a chemical equation throughout, the corresponding equilibrium constant will be the square of the original

## G.C.E. (A/L) CHEMISTRY: UNIT 12 Chemical Equilibrium

value; if you triple the equation, the equilibrium constant will be the cube of the original value, and so on.

In general, if all the coefficients in a balanced chemical equation are subsequently multiplied by $n$, then the new equilibrium constant is the original equilibrium constant is raised to the $\boldsymbol{n}^{\text {th }}$ power.

## Example 2.2

At 800 K , equilibrium constant $\boldsymbol{K}$ for the reaction $\mathrm{N}_{2}(\mathrm{~g})+3 \mathrm{H}_{2}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{NH}_{3}(\mathrm{~g})$ is 0.25 . What is the equilibrium constant $K$ "for the reaction $1 / 2 \mathrm{~N}_{2}(\mathrm{~g})+3 / 2 \mathrm{H}_{2}(\mathrm{~g}) \rightleftharpoons \mathrm{NH}_{3}(\mathrm{~g})$ at 800 K ?

Answer
We can write
$K=\frac{\left[\mathrm{NH}_{3(\mathrm{~g})}\right]^{2}}{\left[\mathrm{~N}_{2(\mathrm{~g})}\right]\left[\mathrm{H}_{2(\mathrm{~g})}\right]^{3}}$

$$
K^{\prime \prime}=\frac{\left[\mathrm{NH}_{3(\mathrm{~g})}\right]}{\left[\mathrm{N}_{2(\mathrm{~g})}\right]^{1 / 2}\left[\mathrm{H}_{2(\mathrm{~g})}\right]^{3 / 2}}=K^{1 / 2}=(0.25)^{\frac{1}{2}}=0.50
$$

### 2.1.7 Equilibrium constant in gaseous systems

So far we have expressed equilibrium constant of the reactions in terms of molar concentration of the reactants and products, and used symbol, $\boldsymbol{K}_{\boldsymbol{c}}$ for it. For reactions involving gases, however, it is usually more convenient to express the equilibrium constant in terms of partial pressures.

As we know, at constant temperature the pressure $\boldsymbol{P}$ of a gas is directly related to the concentration in $\mathbf{m o l ~ d m}{ }^{-3}$ of the gas; that is, $P=(n / V) R T$ or $P=\mathrm{CRT}$. Thus, for the equilibrium, $\mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{NO}_{2}(\mathrm{~g})$, we can write,

$$
\boldsymbol{K}_{\mathbf{p}}=\frac{\left(P_{\mathrm{NO}_{2(\mathrm{~g})}}\right)^{2}}{\left(P_{\mathrm{N}_{2} \mathrm{O}_{4(\mathrm{~g})}}\right)}
$$

Where $P_{\mathrm{NO}_{2(\mathrm{~g})}}$ and $P_{\mathrm{N}_{2} \mathrm{O}_{4(\mathrm{~g})}}$ are the equilibrium partial pressures (in Pa ) of $\mathrm{NO}_{2}(\mathrm{~g})$ and $\mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g})$, respectively. The subscript in $\boldsymbol{K}_{\mathbf{p}}$ indicates that equilibrium concentrations are expressed in terms of pressure. In general, $\boldsymbol{K}_{\mathbf{c}}$ is not always equal to $\boldsymbol{K}_{\mathbf{p}}$, since the partial pressures of reactants and products are not equal to their concentrations expressed in $\mathbf{m o l} \mathbf{d m}^{-3}$. At a constant temperature, a simple relationship between $\boldsymbol{K}_{\mathbf{p}}$ and $\boldsymbol{K}_{\mathbf{c}}$ can be derived as follows. First, let us consider the following equilibrium in the gas phase:

## G.C.E. (A/L) CHEMISTRY: UNIT 12 Chemical Equilibrium

$$
\mathrm{H}_{2}(\mathrm{~g})+\mathrm{I}_{2}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{HI}_{(\mathrm{g})}
$$

We can write,

$$
\begin{aligned}
& \boldsymbol{K}_{\mathbf{c}}=\frac{[\mathrm{HI}(\mathrm{~g})]^{2}}{\left[\mathrm{I}_{2}(\mathrm{~g})\right]\left[\mathrm{H}_{2}(\mathrm{~g})\right]} \\
& \boldsymbol{K}_{\mathbf{p}}=\frac{\left(P_{\mathrm{HI}(\mathrm{~g})}\right)^{2}}{\left(P_{\mathrm{H}_{2}(\mathrm{~g})}\right)\left(P_{\mathrm{I}_{2}(\mathrm{~g})}\right)}
\end{aligned}
$$

Applying $\boldsymbol{P}=\boldsymbol{C R T}$ relation, we can write,
$P_{\mathrm{HI}(\mathrm{g})}=[\mathrm{HI}(\mathrm{g})] R T, P_{\mathrm{H}_{2(\mathrm{~g})}}=\left[\mathrm{H}_{2}(\mathrm{~g})\right] R T$ and $P_{\mathrm{I}_{2(\mathrm{~g})}}=\left[\mathrm{I}_{2}(\mathrm{~g})\right] R T$ and substituting these in

$$
\boldsymbol{K}_{\mathbf{p}}=\frac{\left(P_{\mathrm{HI}(\mathrm{~g})}\right)^{2}}{\left(P_{\mathrm{H}_{2}(\mathrm{~g})}\right)\left(P_{\mathrm{I}_{2}(\mathrm{~g})}\right)}=\frac{[\mathrm{HI}(\mathrm{~g})]^{2}(R T)^{2}}{\left[\mathrm{I}_{2}(\mathrm{~g})\right](R T)\left[\mathrm{H}_{2}(\mathrm{~g})\right](R T)}=\frac{[\mathrm{HI}(\mathrm{~g})]^{2}(R T)^{(2-2)}}{\left[\mathrm{I}_{2}(\mathrm{~g})\right]\left[\mathrm{H}_{2}(\mathrm{~g})\right]}=\boldsymbol{K}_{\mathbf{c}}
$$

In this example, $\boldsymbol{K} \boldsymbol{p}=\boldsymbol{K} \boldsymbol{c}$ i.e., both equilbrium constants are equal. However, this is not always the case. For example in reaction, $\mathrm{N}_{2}(\mathrm{~g})+3 \mathrm{H}_{2}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{NH}_{3}(\mathrm{~g})$,

$$
K_{\mathrm{c}}=\frac{\left[\mathrm{NH}_{3}(\mathrm{~g})\right]^{2}}{\left[\mathrm{~N}_{2}(\mathrm{~g})\right]\left[\mathrm{H}_{2}(\mathrm{~g})\right]^{3}} \text { and } K_{\mathrm{p}}=\frac{\left(P_{\mathrm{NH}_{3}(\mathrm{~g})}\right)^{2}}{\left(P_{\mathrm{N}_{2}(\mathrm{~g})}\right)\left(P_{\mathrm{H}_{2}(\mathrm{~g})}\right)^{3}}
$$

Assuming ideal behaviour,

$$
\begin{aligned}
K_{\mathrm{p}} & =\frac{\left[\mathrm{NH}_{3}(\mathrm{~g})\right]^{2}(R T)^{2}}{\left[\mathrm{~N}_{2}(\mathrm{~g})\right](R T)\left[\mathrm{H}_{2}(\mathrm{~g})\right]^{3}(R T)^{3}} \\
& =\frac{\left[\mathrm{NH}_{3}(\mathrm{~g})\right]^{2}(R T)^{(2-4)}}{\left[\mathrm{N}_{2}(\mathrm{~g})\right]\left[\mathrm{H}_{2}(\mathrm{~g})\right]^{3}} \\
& =\frac{\left[\mathrm{NH}_{3}(\mathrm{~g})\right]^{2}(R T)^{(-2)}}{\left[\mathrm{N}_{2}(\mathrm{~g})\right]\left[\mathrm{H}_{2}(\mathrm{~g})\right]^{3}}
\end{aligned}
$$

and hence we can write,

$$
K_{\mathrm{p}}=K_{\mathrm{c}}(R T)^{-2}
$$

With the impression derived from the above two examples, we can now consider a general case for a gas phase reaction, $\mathrm{aA}(\mathrm{g}) \rightleftharpoons \mathrm{bB}(\mathrm{g})$,

$$
K_{\mathrm{c}}=\frac{[\mathrm{B}(\mathrm{~g})]^{\mathrm{b}}}{[\mathrm{~A}(\mathrm{~g})]^{\mathrm{a}}} \text { and } K_{\mathrm{p}}=\frac{\left(\mathrm{P}_{\mathrm{B}(\mathrm{~g})}\right)^{\mathrm{b}}}{\left(\mathrm{P}_{\mathrm{A}(\mathrm{~g})}\right)^{\mathrm{a}}}
$$

where $P_{\mathrm{A}}$ and $P_{\mathrm{B}}$ are the partial pressures of A and B . Assuming ideal gas behavior in a closed rigid container of volume $V \mathrm{dm}^{3}$ at temperature $T(\mathrm{~K})$,
$P_{\mathrm{A}} V=n_{\mathrm{A}} R T$ and $P_{\mathrm{B}} V=n_{\mathrm{B}} R T$.
Therefore we can write
$P_{\mathrm{A}}=C_{\mathrm{A}} R T$ and $P_{\mathrm{B}}=C_{\mathrm{B}} R T$ and when the $C_{\mathrm{A}}$ and $C_{\mathrm{B}}$ are expressed in mol dm${ }^{-3}$,

$$
\begin{gathered}
P_{\mathrm{A}}=[\mathrm{A}] R T \text { and } P_{\mathrm{B}}=[\mathrm{B}] R T \text { substituting in } K_{\mathrm{p}} \text { expression above, } \\
\qquad \begin{array}{c}
K_{\mathrm{p}}=\frac{([\mathrm{B}] R T)^{\mathrm{b}}}{([\mathrm{~A}] R T)^{\mathrm{a}}}=\frac{[\mathrm{B}]^{\mathrm{b}}}{[\mathrm{~A}]^{\mathrm{a}}}(R T)^{\mathrm{b}-\mathrm{a}}=K_{\mathrm{c}}(R T)^{\mathrm{b}-\mathrm{a}} \\
=K_{C}(R T)^{\Delta n}, \text { where } \Delta n=\mathrm{b}-\mathrm{a} \\
\boldsymbol{K}_{\mathbf{p}}=\boldsymbol{K}_{\mathbf{c}}(R T)^{\Delta n}
\end{array}
\end{gathered}
$$

As a summary we can write the relation between $\boldsymbol{K}_{\boldsymbol{P}}$ and $\boldsymbol{K}_{\boldsymbol{C}}$ for a reaction,
$\mathrm{aA}+\mathrm{bB} \rightleftharpoons \mathrm{cC}+\mathrm{dD}$ as,

$$
K_{\mathbf{p}}=K_{\mathbf{c}}(R T)^{(\mathbf{c}+\mathrm{d})-(\mathbf{a}+\mathbf{b})}=K_{\mathbf{c}}(R T)^{\Delta n}
$$

$\Delta n=$ amount of moles of gaseous products - amount of moles of gaseous reactants
In general, $K_{\mathrm{p}} \neq K_{\mathrm{c}}$ except in the special case(s) as shown above for the example with $\mathrm{H}_{2}(\mathrm{~g})+\mathrm{I}_{2}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{HI}(\mathrm{g})$ system in which $\Delta n=0$.

Note: It is general practice not to include units for the equilibrium constant. In thermodynamics, $K$ is defined as having no units because every concentration (molarity) or pressure (atm/Pa) term is actually a ratio to a standard value, which is $1 \mathrm{~mol} \mathrm{dm}^{-3}$ or $1 \mathrm{~atm} / 101325 \mathrm{~Pa}(\sim 100 \mathrm{kPa}$ ). This procedure eliminates all units but does not alter the numerical parts of the concentration or pressure. Consequently, $K$ has no units.

However, in the case when every concentration (molarity) or pressure (atm/Pa) term is not a ratio to the standard value, that procedure will append appropriate units for the equilibrium constant(s).
i.e. Equilibrium constants can also be expressed as dimensionless quantities if the standard state of reactants and products are specified. For a pure gas, the standard state is $1 \mathrm{bar}\left(P^{\ominus}=1 \mathrm{~atm}, 100 \mathrm{kPa}\right)$. Therefore a pressure of 400 kPa in standard state can be expressed as $400 \mathrm{kPa} / 100 \mathrm{kPa}=4$, which is a dimensionless number. Standard state $\left(C^{\theta}\right)$ for a solute in a solution is $1.0 \mathrm{~mol} \mathrm{dm}^{-3}$. All concentrations can be measured with respect to it. The numerical value of equilibrium constant depends on the standard state chosen. Though the equilibrium constants are considered dimensionless/ unitless quantities, in this text we consider the concentrations and pressures with their respective units unless the standard state is mentioned.

The value of equilibrium constant $K_{\mathrm{c}}$ can be calculated by substituting the concentration terms in $\mathbf{~ m o l ~ d m}{ }^{-3}$ and for $K_{\mathrm{p}}$ partial pressure can be substituted in $\mathbf{P a}, \mathbf{k P a}$, bar or $\mathbf{a t m}$. This results in units of equilibrium constant based on molarity or pressure, unless the exponents of both the numerator and denominator are the same.

## G.C.E. (A/L) CHEMISTRY: UNIT 12 Chemical Equilibrium

For the reactions,
$\mathrm{H}_{2}(\mathrm{~g})+\mathrm{I}_{2}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{HI}(\mathrm{g}), K_{\mathrm{c}}$ and $K_{\mathrm{p}}$ have no unit.
$\mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{NO}_{2}(\mathrm{~g}), K_{\mathrm{c}}$ has unit mol dm${ }^{-3}$ and $K_{\mathrm{p}}$ has unit Pa.

## Example 2.3

Methane gas $\left(\mathrm{CH}_{4}\right)$ reacts with hydrogen sulfide gas at 1000 K to yield $\mathrm{H}_{2}$ and carbon disulfide as $\mathrm{CH}_{4}(\mathrm{~g})+2 \mathrm{H}_{2} \mathrm{~S}(\mathrm{~g}) \rightleftharpoons \mathrm{CS}_{2}(\mathrm{~g})+4 \mathrm{H}_{2}(\mathrm{~g})$
What are the value of $K_{P}$ and $K_{C}$ at 1000 K if the partial pressures in an equilibrium mixture at 1000 K are $0.20 \times 10^{5} \mathrm{~Pa}$ of $\mathrm{CH}_{4}, 0.25 \times 10^{5} \mathrm{~Pa}$ of $\mathrm{H}_{2} \mathrm{~S}, 0.52 \times 10^{5} \mathrm{~Pa}$ of $\mathrm{CS}_{2}$ and $0.10 \times 10^{5} \mathrm{~Pa}$ of $\mathrm{H}_{2}$ ?

## Answer

$$
\begin{aligned}
& K_{\mathrm{p}}=\frac{\left(P_{\mathrm{H}_{2}(\mathrm{~g})}\right)^{4}\left(P_{\mathrm{CS}_{2}(\mathrm{~g})}\right)}{\left(\mathrm{P}_{\mathrm{CH}_{4}(\mathrm{~g})}\right)\left(P_{\mathrm{H}_{2} \mathrm{~S}(\mathrm{~g})}\right)^{2}}=\frac{(0.1 \mathrm{~Pa})^{4}(0.52 \mathrm{~Pa})}{(0.20 \mathrm{~Pa})(0.25 \mathrm{~Pa})^{2}}\left(1.0 \times 10^{5} \mathrm{~Pa}\right)^{2} \\
& =4.2 \times 10^{-3} \times 10^{10} \mathrm{~Pa}^{2}=4.2 \times 10^{7} \mathrm{~Pa}^{2} \\
& K_{\mathrm{p}}=K_{\mathrm{c}}(R T)^{\Delta n} \\
& \begin{aligned}
& \Delta n= 5-3=2 \\
& \text { Therefore, } K_{\mathrm{p}}=K_{\mathrm{c}}(R T)^{2} \text { and } K_{\mathrm{c}}=\frac{K_{P}}{(R T)^{2}} \\
& \quad \begin{array}{l}
K_{\mathrm{c}}
\end{array}=\frac{K_{P}}{(R T)^{2}}=\frac{4.2 \times 10^{7} \mathrm{~Pa}^{2}}{\left(8.314 \mathrm{~J} \mathrm{~K}^{-1} \mathrm{~mol}^{-1} \times 1000 \mathrm{~K}\right)^{2}}=\frac{4.2 \times 10^{7}\left(10^{-3} \mathrm{Jdm}^{-3}\right)^{2}}{\left(8314 \mathrm{~J} \mathrm{~mol}^{-1}\right)^{2}} \\
& \quad=6 \times 10^{-7} \mathrm{~mol}^{2} \mathrm{dm}^{-6}
\end{aligned}
\end{aligned}
$$

However, if the partial pressures are defined as $P / P^{\theta}$, where $P^{\theta}$ is the standard pressure of 1 atm or $1.0 \times 10^{5} \mathrm{~Pa}$, we will have

$$
K_{\mathrm{p}}=\frac{\left(\frac{P_{\mathrm{H}_{2}}(\mathrm{~g})}{P^{a}}\right)^{4}\left(\frac{{ }_{C \mathrm{CS}_{2}(\mathrm{~g})}}{P^{a}}\right)}{\left(\frac{{ }_{C H_{4}(\mathrm{~g})}}{P^{a}}\right)\left(\frac{\left({ }_{\mathrm{H}_{2} S}(\mathrm{~g})\right.}{P^{a}}\right)^{2}}=\frac{(0.1)^{4}(0.52)}{(0.20)(0.25)^{2}}=4.2 \times 10^{-3}
$$

Consider the ionization of acetic acid $\left(\mathrm{CH}_{3} \mathrm{COOH}\right)$ in water as another example for a homogeneous equilibrium.

$$
\mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})+\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})
$$

The equilibrium constant is; $\quad K_{\mathrm{c}}^{\prime}=\frac{\left[\mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})\right]}{\left[\mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})\right]}\left[\begin{array}{l}{\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]} \\ \hline \mathrm{O}(\mathrm{l})]\end{array}\right.$
Here, liquid water, $\mathrm{H}_{2} \mathrm{O}(\mathrm{l})$ is present as a medium for the reaction. In $1 \mathrm{dm}^{3}(1 \mathrm{~L}$, or 1000 g of water, there are $1000 \mathrm{~g} /\left(18 \mathrm{~g} \mathrm{~mol}^{-1}\right)$ or 55.5 moles, of water. Therefore, the "concentration" of water or $\left[\mathrm{H}_{2} \mathrm{O}(\mathrm{l})\right]$ is $55.5 \mathrm{~mol} \mathrm{dm}^{-3}$. This is a large quantity compared to the concentrations of other species in solution (usually $1 \mathrm{~mol} \mathrm{dm}^{-3}$ or smaller), and we
can assume that it does not change appreciably during the course of a reaction. Thus we may treat $\left[\mathrm{H}_{2} \mathrm{O}(\mathrm{l})\right]$ as a constant. Therefore, we can write the equilibrium constant as;

$$
K_{\mathrm{c}}=\frac{\left[\mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})\right]\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]}{\left[\mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})\right]}
$$

Where, $K_{\mathrm{c}}=K_{\mathrm{c}}^{\prime}\left[\mathrm{H}_{2} \mathrm{O}(\mathrm{l})\right]$

### 2.1.8 Heterogeneous equilibria

Equilibrium in a system having more than one phase is called a heterogeneous equilibrium. The equilibrium between water vapour and liquid water in a closed container is an example of a heterogeneous equilibrium.

$$
\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{H}_{2} \mathrm{O}(\mathrm{~g})
$$

In this example, there is a gas phase and a liquid phase. In the same way, equilibrium between a solid and its saturated solution is a heterogeneous equilibrium.

$$
\mathrm{Ca}(\mathrm{OH})_{2}(\mathrm{~s}) \rightleftharpoons \mathrm{Ca}^{2+}(\mathrm{aq})+2 \mathrm{OH}^{-}(\mathrm{aq})
$$

Heterogeneous equilibria often involve pure solids or liquids. We can simplify equilibrium expressions for the heterogeneous equilibria involving a pure liquid or a pure solid, as the molar concentration of a pure solid or liquid is constant (i.e., independent of the amount present). Let us consider thermal decomposition of calcium carbonate as an example for heterogeneous chemical equilibrium.

$$
\mathrm{CaCO}_{3}(\mathrm{~s}) \rightleftharpoons \mathrm{CaO}(\mathrm{~s})+\mathrm{CO}_{2}(\mathrm{~g})
$$

Considering the stoichiometric equation, we can write,

$$
K_{\mathrm{c}}^{\prime}=\frac{[\mathrm{CaO}(\mathrm{~s})]\left[\mathrm{CO}_{2}(\mathrm{~g})\right]}{\left[\mathrm{CaCO}_{3}(\mathrm{~s})\right]}
$$

Because the molar concentrations of pure liquids and solids normally do not vary greatly with temperature, their concentrations are treated as constants, which allows us to simplify equilibrium constant expressions that involve pure solids or liquids.The reference states for pure solids and liquids are those forms stable at $100 \mathrm{kPa} / 1 \mathrm{~atm}$, which are assigned an activity (effective mass) of 1. i.e. the "concentration" of a solid, like its density, is an intensive property and does not depend on how much of the substance is present.
In the above example, since $\left[\mathrm{CaCO}_{3(\mathrm{~s})}\right]$ and $[\mathrm{CaO}(\mathrm{s})]$ are both constants, the modified equilibrium constant for the thermal decomposition of calcium carbonate will be

$$
K_{\mathrm{c}}=\left[\mathrm{CO}_{2(\mathrm{~g})}\right],
$$

where,

$$
K_{\mathrm{c}}=K_{\mathrm{c}}^{\prime} \frac{\left[\mathrm{CaCO}_{3}(\mathrm{~s})\right]}{[\mathrm{CaO}(\mathrm{~s})]} \text { is a constant. }
$$

Likewise we can write $\quad K_{\mathrm{p}}=P_{\mathrm{CO}_{2}(\mathrm{~g})}$
For reactions carried out in solution, the concentration of the solvent is omitted from the equilibrium constant expression even when the solvent appears in the balanced chemical equation for the reaction. The concentration of the solvent is also typically much greater than the concentration of the reactants or products (recall that for pure water it is about $55.5 \mathrm{~mol} \mathrm{dm}^{-3}$ and for pure ethanol it is about $17 \mathrm{~mol} \mathrm{dm}^{-3}$ ). Consequently, the solvent concentration is essentially constant during chemical reactions, and the solvent is therefore treated as a pure liquid. The equilibrium constant expression for a reaction contains only those species whose concentrations could change significantly during the reaction.

In the reaction,

$$
\begin{gathered}
\mathrm{Hg}(\mathrm{l})+\mathrm{Hg}^{2+}(\mathrm{aq}) \rightleftharpoons \mathrm{Hg}_{2}^{2+}(\mathrm{aq}) \\
K_{\mathrm{c}}^{\prime}=\frac{\left[\mathrm{Hg}_{2}^{2+}(\mathrm{aq})\right]}{\left[\mathrm{Hg}^{2+}(\mathrm{aq})\right][\mathrm{Hg}(\mathrm{l})]} \text { and we can write, } \\
K_{\mathrm{c}}=\frac{\left[\mathrm{Hg}_{2}^{2+}(\mathrm{aq})\right]}{\left[\mathrm{Hg}^{2+}(\mathrm{aq})\right]} \text { where, } K_{\mathrm{c}}=K_{\mathrm{c}}^{\prime}[\mathrm{Hg}(\mathrm{l})]
\end{gathered}
$$

In this case, it's not appropriate to write an expression for $\boldsymbol{K}_{\mathbf{p}}$ because none of the reactants and products is a gas.

In summary, it is clear that in a systems of a heterogeneous equilibrium, pure solids or liquids must be present for the equilibrium to exist, but their concentrations or partial pressures do not appear in the expression of the equilibrium constant. In the reaction below, we can see that though a solid reactant is present and liquid water is produced, the equilibrium constant expression does not contain both.

$$
\begin{gathered}
\mathrm{Ag}_{2} \mathrm{O}(\mathrm{~s})+2 \mathrm{HNO}_{3}(\mathrm{aq}) \rightleftharpoons 2 \mathrm{AgNO}_{3}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \\
K_{C}=\frac{\left[\mathrm{AgNO}_{3}(\mathrm{aq})\right]^{2}}{\left[\mathrm{HNO}_{3}(\mathrm{aq})\right]^{2}}
\end{gathered}
$$

Note: The concentrations of pure solids, pure liquids, and solvents are omitted from equilibrium constant expressions because they do not change significantly during reactions when enough is present to reach equilibrium.

### 2.1.9 Equilibrium constant expressions for multi-step reactions

It is essential to know the equilibrium constant for a reaction that has not been previously studied or the desired reaction occurs in several steps. In such cases, the desired reaction can often be written as the sum of other reactions for which the equilibrium constants are known. The equilibrium constant for the unknown reaction can then be calculated from the tabulated or available values of the other reactions.

For example, consider the system $\mathrm{A}+\mathrm{B} \rightleftharpoons \mathrm{E}+\mathrm{F}$ in which the products formed in the first reaction, C and D , react further to form products E and F . At equilibrium we can write two separate equilibrium constants for the reactions,

$$
\begin{gathered}
\mathrm{A}+\mathrm{B} \rightleftharpoons \mathrm{C}+\mathrm{D} \\
\mathrm{C}+\mathrm{D} \rightleftharpoons \mathrm{E}+\mathrm{F} \\
K_{\mathrm{c}}^{\prime}=\frac{[\mathrm{C}][\mathrm{D}]}{[\mathrm{A}][\mathrm{B}]} \text { and } K_{\mathrm{c}}^{\prime \prime}=\frac{[\mathrm{E}][\mathrm{F}]}{[\mathrm{C}][\mathrm{D}]}
\end{gathered}
$$

We can see that the sum of the two reactions results the overall reaction and hence,

$$
\begin{aligned}
& \mathrm{A}+\mathrm{B} \rightleftharpoons \mathrm{C}+\mathrm{D} \\
& \mathrm{C}+\mathrm{D} \rightleftharpoons \mathrm{E}+\mathrm{F} \\
& \hline \mathrm{~A}+\mathrm{B} \rightleftharpoons \mathrm{E}+\mathrm{F}
\end{aligned}
$$

The equilibrium constant for the overall reaction is,

$$
K_{\mathrm{c}}=\frac{[\mathrm{E}][\mathrm{F}]}{[\mathrm{A}][\mathrm{B}]}
$$

We can see that the expression of $K_{\mathrm{c}}$ is the product of $K_{\mathrm{c}}^{\prime}$ and $K_{\mathrm{c}}^{\prime \prime}$

$$
K_{\mathrm{c}}^{\prime} K_{\mathrm{c}}^{\prime \prime}=\frac{[\mathrm{C}][\mathrm{D}]}{[\mathrm{A}][\mathrm{B}]} \times \frac{[\mathrm{E}][\mathrm{F}]}{[\mathrm{C}][\mathrm{D}]}=\frac{[\mathrm{E}][\mathrm{F}]}{[\mathrm{A}][\mathrm{B}]}
$$

Therefore,

$$
K_{\mathrm{c}}=K_{\mathrm{c}}^{\prime} K_{\mathrm{c}}^{\prime \prime}
$$

Note: If a reaction can be expressed as the sum of two or more reactions, the equilibrium constant for the overall reaction is given by the product of the equilibrium constants of the individual reactions.

For example, let's consider the reaction of $\mathrm{N}_{2}(\mathrm{~g})$ with $\mathrm{O}_{2}(\mathrm{~g})$ to give $\mathrm{NO}_{2}(\mathrm{~g})$ at $100{ }^{\circ} \mathrm{C}$. The reaction normally occurs in two distinct steps. In the first reaction (I), $\mathrm{N}_{2}(\mathrm{~g})$ reacts with $\mathrm{O}_{2}(\mathrm{~g})$ to give $\mathrm{NO}(\mathrm{g})$. The $\mathrm{NO}(\mathrm{g})$ produced then reacts with additional $\mathrm{O}_{2}(\mathrm{~g})$ to give $\mathrm{NO}_{2}(\mathrm{~g})$ as in reaction (II). Assume also that the concentrations are measured with respect to the standard molarity i.e. $C^{\ominus}=1.0 \mathrm{~mol} \mathrm{dm}^{-3}$.

$$
\begin{array}{rll}
\mathrm{N}_{2}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{NO}(\mathrm{~g}): & & K_{\mathrm{c}}^{\prime}=2.0 \times 10^{-25} \ldots \ldots .(\mathrm{I}) \\
2 \mathrm{NO}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{NO}_{2}(\mathrm{~g}): & & K_{\mathrm{c}}^{\prime \prime}=6.4 \times 10^{9} \ldots \ldots .(\mathrm{II}) \tag{II}
\end{array}
$$

Summing reactions (I) and (II) gives the overall reaction:

$$
\begin{gathered}
\mathrm{N}_{2}(\mathrm{~g})+2 \mathrm{O}_{2}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{NO}_{2}(\mathrm{~g}) \quad K_{\mathrm{c}}=? \\
K_{\mathrm{c}}^{\prime}=\frac{[\mathrm{NO}(\mathrm{~g})]^{2}}{\left[\mathrm{~N}_{2}(\mathrm{~g})\right]\left[\mathrm{O}_{2}(\mathrm{~g})\right]}=2.0 \times 10^{-25} \text { and } K_{\mathrm{c}}^{\prime \prime}=\frac{\left[\mathrm{NO}_{2}(\mathrm{~g})\right]^{2}}{\left[\mathrm{NO}_{0}(\mathrm{~g})\right]^{2}[\mathrm{O}(\mathrm{~g})]}=6.4 \times 10^{9} \\
K_{\mathrm{c}}^{\prime} \times K_{\mathrm{c}}^{\prime \prime}=\frac{[\mathrm{NO}(\mathrm{~g})]^{2}}{\left[\mathrm{~N}_{2}(\mathrm{~g})\right]\left[\mathrm{O}_{2}(\mathrm{~g})\right]} \times \frac{\left[\mathrm{NO}_{2}(\mathrm{~g})\right]^{2}}{\left[{\mathrm{NO}(\mathrm{~g})]^{2}\left[\mathrm{O}_{2}(\mathrm{~g})\right]}^{2}\right.}=\frac{\left[\mathrm{NO}_{2}(\mathrm{~g})\right]^{2}}{\left[\mathrm{O}_{2}(\mathrm{~g})\right]^{2}\left[\mathrm{~N}_{2}(\mathrm{~g})\right]}=K_{\mathrm{c}}
\end{gathered}
$$

## G.C.E. (A/L) CHEMISTRY: UNIT 12 Chemical Equilibrium

Therefore, $K_{\mathrm{c}}=\underset{\mathrm{c}}{\prime} \times K_{\mathrm{c}}^{\prime \prime}=\left(2.0 \times 10^{-25}\right)\left(6.4 \times 10^{9}\right)=1.28 \times 10^{-15}$

Note: The relation among equilibrium constants of multi-step reactions can also be understood by the principles of chemical kinetics as described in Unit 11.

Consider the above example of the reaction $\mathrm{A}+\mathrm{B} \rightleftharpoons \mathrm{E}+\mathrm{F}$.
Suppose the same reaction has a mechanism with two elementary steps.

$$
\mathrm{A}+\mathrm{B} \underset{k_{r}^{\prime}}{\stackrel{k_{f}^{\prime}}{\rightleftharpoons}} \mathrm{C}+\mathrm{D}
$$

We can write, $K_{\mathrm{c}}^{\prime}=\frac{\grave{k}_{f}^{\prime}}{k_{r}^{\prime}}=\frac{[\mathrm{C}][\mathrm{D}]}{[\mathrm{A}][\mathrm{B}]}$ and $K_{\mathrm{c}}^{\prime \prime}=\frac{k^{\prime \prime}}{k_{f}^{\prime \prime}}=\frac{[\mathrm{E}][\mathrm{F}]}{[\mathrm{C}][\mathrm{D}]}$

$$
K_{\mathrm{c}}^{\prime} K_{\mathrm{c}}^{\prime \prime}=\frac{k_{f}^{\prime}}{k_{r}^{\prime}} \times \frac{k_{f}^{\prime \prime}}{k_{r}^{\prime \prime}}=\frac{[\mathrm{C}][\mathrm{D}]}{[\mathrm{A}][\mathrm{B}]} \times \frac{[\mathrm{E}][\mathrm{F}]}{[\mathrm{C}][\mathrm{D}]}=\frac{[\mathrm{E}][\mathrm{F}]}{[\mathrm{A}][\mathrm{B}]}=K_{\mathrm{c}}
$$

In summary the followings are the key points to remember.

- The equilibrium constant is a constant at a given temperature, or it depends on the temperature.
- The concentrations of the reacting species in the condensed phase are expressed in $\mathbf{m o l} \mathbf{d m}^{-3}$. In the gaseous phase, the concentrations can be expressed in $\mathbf{m o l} \mathbf{d m}^{-3}$ or in $\mathbf{P a}(\mathrm{atm})$. $\boldsymbol{K}_{\mathbf{c}}$ is related to $\boldsymbol{K}_{\mathbf{p}}$ by a simple equation of

$$
K_{\mathbf{p}}=K_{\mathbf{c}}(R T)^{\Delta n}
$$

- The concentrations of pure solids, pure liquids (in heterogeneous equilibria), and solvents (in homogeneous equilibria) do not appear in the equilibrium constant expressions.
- The equilibrium constant ( $\boldsymbol{K}_{\mathbf{c}}$ or $\boldsymbol{K}_{\mathbf{p}}$ ) is a dimensionless quantity when the standard condition is used.
- In quoting a value for the equilibrium constant, we must specify the balanced equation and the temperature.
- If a reaction can be expressed as the sum of two or more reactions, the equilibrium constant for the overall reaction is given by the product of the equilibrium constants of the individual reactions.
- The value of $\boldsymbol{K}$ also depends on how the equilibrium equation is balanced. According to the law of mass action, each concentration term in the equilibrium constant expression is raised to a power equal to its stoichiometric coefficient. Thus if you double a chemical equation throughout, the corresponding equilibrium constant will be the square of the original value; if you triple the equation, the equilibrium constant
will be the cube of the original value, and so on. i.e. In general, if all the coefficients in a balanced chemical equation are subsequently multiplied by $n$, then the new equilibrium constant is the original equilibrium constant raised to the $\boldsymbol{n}^{\text {th }}$ power.

### 2.1.10 Predicting the direction of reaction and calculations based on equilibrium constant

We have seen that the equilibrium constant for a given reaction can be calculated from known equilibrium concentrations. Given the equilibrium constant and the initial concentrations of reactants, we can calculate the concentration of one or more substances at equilibrium only if the temperature does not change. In general, the magnitude of the equilibrium constant helps us to predict the direction in which a reaction mixture will proceed to achieve equilibrium and to calculate the concentrations of reactants and products once the equilibrium is reached. These uses of the equilibrium constant will be explored in this section.

## Predicting the direction of a reaction

The equilibrium constant helps in predicting the direction in which a given reaction will proceed at any stage. For this purpose, we calculate the reaction quotient $Q$ by substituting the initial concentrations in the equilibrium constant expression. The reaction quotient, $\boldsymbol{Q}\left(\boldsymbol{Q}_{C}\right.$ with molar concentrations and $\boldsymbol{Q}_{p}$ with partial pressures) is defined in the same way as the equilibrium constant $\boldsymbol{K}_{\boldsymbol{c}}$ except that the concentrations in $\boldsymbol{Q}_{C}$ are not necessarily to be equilibrium values.

For a general reaction:

$$
\begin{aligned}
\mathrm{aA}+\mathrm{bB} & \rightleftharpoons \mathrm{cC}+\mathrm{dD} \\
Q_{c}= & \frac{[\mathrm{C}]_{t}^{\mathrm{c}}[\mathrm{D}]_{t}^{\mathrm{d}}}{[\mathrm{~A}]_{t}^{\mathrm{a}}[\mathrm{~B}]_{t}^{\mathrm{b}}}
\end{aligned}
$$

Here subscript $\boldsymbol{t}$ means that the concentrations are measured at an arbitrary time $\boldsymbol{t}$ and not necessarily at equilibrium. The reaction quotient $\boldsymbol{Q}$ is useful because it helps us predict the direction of reaction by comparing the values of $Q_{c}$ and $K_{c}$. If $Q_{c}$ is less than $K_{\mathrm{c}}\left(Q_{\mathrm{c}}<K_{\mathrm{c}}\right)$, movement toward equilibrium increases by converting reactants to products (that is, net reaction proceeds from left to right). If $Q_{\mathrm{c}}$ is greater than $K_{\mathrm{c}}\left(Q_{\mathrm{c}}>\right.$ $K_{\mathrm{c}}$ ), movement toward equilibrium decreases by converting products to reactants (that is, net reaction proceeds from right to left). If $Q_{c}$ equals $K_{c}\left(Q_{c}=K_{c}\right)$, the reaction mixture is already at equilibrium, and no net reaction occurs. Thus, we can make the following generalizations concerning the direction of the reaction:

- $Q_{c}>K_{\mathrm{c}}$ : The ratio of initial concentrations of products to reactants is too large. To reach equilibrium, products must be converted to reactants. The system

## G.C.E. (A/L) CHEMISTRY: UNIT 12 Chemical Equilibrium

proceeds from right to left (consuming products, forming reactants) to reach equilibrium.

- $Q_{\mathrm{c}}=K_{\mathrm{c}}$ : The initial concentrations are equilibrium concentrations. The system is at equilibrium.
- $Q_{\mathrm{c}}<K_{\mathrm{c}}$ : The ratio of initial concentrations of products to reactants is too small. To reach equilibrium, reactants must be converted to products. The system proceeds from left to right (consuming reactants, forming products) to reach equilibrium.

This can be illustrated by the conceptual diagram shown in Figure 2.7.

Figure 2.7 Different views for the interpretation of the magnitudes of $K$ and $Q:$ (a) compares the magnitudes of $K$ and $Q$, (b) indicates the way that how the direction or equilibrium position of the reaction tends to move with the relative size of $Q$ and (c) compares the composition of the reaction mixture at diferent positions where it can be noted that at equilibrium, $Q=K=1.5$ with the presence of appropriate number of reactant and product molecules in the reaction mixture.

## Example 2.4

The value of $K_{\mathrm{c}}$ for the reaction $2 \mathrm{~A} \rightleftharpoons \mathrm{~B}+\mathrm{C}$ is $2 \times 10^{-3}$. At a given time, the composition of reaction mixture is $[\mathrm{A}]=[\mathrm{B}]=[\mathrm{C}]=3 \times 10^{-4} \mathrm{~mol} \mathrm{dm}^{-3}$. In which direction will the reaction proceed?

## Answer

For the reaction the reaction quotient $Q_{c}$ is given by,
$Q_{\mathrm{c}}=\frac{[\mathrm{B}][\mathrm{C}]}{[\mathrm{A}]^{2}}=\left(3 \times 10^{-4}\right)\left(3 \times 10^{-4}\right) /\left(3 \times 10^{-4}\right)^{2}=1$
$Q_{c}>K_{c}$
Therefore, the reaction will proceed in the reverse direction.

## Example 2.5

At elevated temperatures, methane $\left(\mathrm{CH}_{4}(\mathrm{~g})\right)$ reacts with water to produce hydrogen and carbon monoxide as:

$$
\mathrm{CH}_{4}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{O}(\mathrm{~g}) \rightleftharpoons \mathrm{CO}(\mathrm{~g})+3 \mathrm{H}_{2}(\mathrm{~g})
$$

Equilibrium constant for the reaction is $K=2.4 \times 10^{-4}$ at 900 K . If, $1.2 \times 10^{-2}$ moles of $\mathrm{CH}_{4}, 8.0 \times 10^{-3}$ moles of $\mathrm{H}_{2} \mathrm{O}, 1.6 \times 10^{-2}$ moles of CO and $6.0 \times 10^{-3}$ moles of $\mathrm{H}_{2}$ are placed in a $2.0 \mathrm{dm}^{3}$ closed rigid reactor and heated to 900 K , will the reaction be at equilibrium or will it proceed to the right to produce CO and $\mathrm{H}_{2}$ or to the left to form $\mathrm{CH}_{4}$ and $\mathrm{H}_{2} \mathrm{O}$ ?

## Answer

First let's find the initial concentrations of the substances present.
For example, we have $1.2 \times 10^{-2}$ moles of $\mathrm{CH}_{4}$ in a $2.0 \mathrm{dm}^{3}$ container, so $\left[\mathrm{CH}_{4}(\mathrm{~g})\right]=1.2 \times 10^{-2} \mathrm{~mol} / 2.0 \mathrm{dm}^{3}=6.0 \times 10^{-3} \mathrm{~mol} \mathrm{dm}^{-3}$

Similarly, we can calculate $\left[\mathrm{H}_{2} \mathrm{O}(\mathrm{g})\right]=4.0 \times 10^{-3} \mathrm{~mol} \mathrm{dm}^{-3},[\mathrm{CO}(\mathrm{g})]=8.0 \times 10^{-3} \mathrm{~mol}$ $\mathrm{dm}^{-3}$, and $\left[\mathrm{H}_{2}(\mathrm{~g})\right]=3.0 \times 10^{-3} \mathrm{~mol} \mathrm{dm}^{-3}$.
$Q_{\mathrm{c}}=\frac{[\mathrm{CO}(\mathrm{g})]\left[\mathrm{H}_{2}(\mathrm{~g})\right]^{3}}{\left[\mathrm{CH}_{4}(\mathrm{~g})\right]\left[\mathrm{H}_{2} \mathrm{O}(\mathrm{g})\right]}$
$=\frac{\left(8 \times 10^{-3}\right)\left(3 \times 10^{-3}\right)^{3}}{\left(6 \times 10^{-3}\right)\left(4 \times 10^{-3}\right)}$
$=9.0 \times 10^{-6}$
$Q_{c}<K\left(2.4 \times 10^{-4}\right)$
Thus the ratio of the concentrations of products to the concentrations of reactants is less than the ratio for an equilibrium mixture. The reaction will therefore proceed to the right as written, forming $\mathrm{H}_{2}$ and CO at the expense of $\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{CH}_{4}$.

## G.C.E. (A/L) CHEMISTRY: UNIT 12 Chemical Equilibrium

## Example 2.6

A mixture of 1.5 mol of $\mathrm{N}_{2}, 2.0 \mathrm{~mol}$ of $\mathrm{H}_{2}$, and 8.0 mol of $\mathrm{NH}_{3}$ is introduced into a $20.0 \mathrm{dm}^{3}$ closed rigid reaction vessel at 500 K . At this temperature, the equilibrium constant for the reaction $\mathrm{N}_{2}(\mathrm{~g})+3 \mathrm{H}_{2}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{NH}_{3}(\mathrm{~g})$, is $1.7 \times 10^{2}$. Is the reaction mixture at equilibrium? If not, what is the direction of the net reaction?

## Answer

The initial concentration of $\left[\mathrm{N}_{2}(\mathrm{~g})\right]$ is $1.5 / 20=7.5 \times 10^{-2} \mathrm{~mol} \mathrm{dm}^{-3}$. Similarly, $\left[\mathrm{H}_{2}(\mathrm{~g})\right]=1.0 \times 10^{-1} \mathrm{~mol} \mathrm{dm}^{-3}$ and $\left[\mathrm{NH}_{3}(\mathrm{~g})\right]=4.0 \times 10^{-1} \mathrm{~mol} \mathrm{dm}^{-1}$. Substituting these concentrations into the $Q$ expression gives

$$
\begin{aligned}
Q_{c} & =\frac{\left[\mathrm{NH}_{3(\mathrm{~g})}\right]^{2}}{\left[\mathrm{~N}_{2(\mathrm{~g})}\right]\left[\mathrm{H}_{2(\mathrm{~g})}\right]^{3}}=\frac{\left(4 \times 10^{-1}\right)^{2}}{\left(7.5 \times 10^{-2}\right)\left(1.0 \times 10^{-1}\right)^{3}} \\
& =2.1 \times 10^{4}
\end{aligned}
$$

Because $Q_{\mathrm{c}}$ does not equal to $K_{\mathrm{c}}$, the reaction mixture is not at equilibrium.

$$
Q_{\mathrm{c}}>K_{\mathrm{c}}
$$

Net reaction will proceed from right to left, decreasing the concentration of $\mathrm{NH}_{3}$ and increasing the concentrations of $\mathrm{N}_{2}$ and $\mathrm{H}_{2}$ until $Q_{\mathrm{c}}=K_{\mathrm{c}}$.

With the knowledge from above examples, we can simply explain how $Q_{\mathrm{c}}$ varies with time as shown in Figure 2.8.

Figure 2.8 The figure explaining the variation of $Q$ over time: If the initial $Q$ is less than $K$ it increases with time favouring the forward reaction; if it is greater than $K$, it decreases with time favouring the backward reaction until the condition is reached at which $Q=K$.

With the help of Figures 2.5 and 2.8, we can note that;
Before equilibrium, $\Delta G<0$ and $Q<K$. The reaction is spontaneous in the forward direction.

## G.C.E. (A/L) CHEMISTRY: UNIT 12 Chemical Equilibrium

At equilibrium, $\Delta G=0$ and $Q=K$.
Beyond the equilibrium position, $\Delta G>0$ and $Q>K$. The reaction is spontaneous in the reverse direction.

Note: The reaction quotient $(Q)$ is used to determine whether a system is at equilibrium and if it is not, to predict the direction of reaction.

### 2.1.11 Calculating equilibrium concentrations

In case of a problem in which we know the initial concentrations but do not know any of the equilibrium concentrations, the following three steps shall be followed:

Step 1. Write the balanced equation for the reaction.
Step 2. Under the balanced equation, make a table that lists for each substance involved in the reaction:
(a) the initial concentration,
(b) the change in concentration $(x)$ on going to equilibrium, and
(c) the equilibrium concentration.

In constructing the table, define $x\left(\right.$ or $\alpha$ ) as the concentration $\left(\mathrm{mol} \mathrm{dm}^{-3}\right)$ (or degree of dissociation) of one of the substances that reacts when going to equilibrium, and then use the stoichiometry of the reaction to determine the concentrations of the other substances in terms of $x$.
Step 3. Substitute the equilibrium concentrations into the equilibrium expression for the reaction and solve for $x$. If you are to solve a quadratic equation choose the mathematical solution that makes chemical sense. Calculate the equilibrium concentrations from the calculated value of $x$.

## Example 2.7

The equilibrium constant $K_{C}$ for the reaction of $\mathrm{H}_{2}(\mathrm{~g})$ with $\mathrm{I}_{2}(\mathrm{~g})$ is 64.0 at 800 K :

$$
\mathrm{H}_{2}(\mathrm{~g})+\mathrm{I}_{2}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{HI}(\mathrm{~g})
$$

If 1.00 mol of $\mathrm{H}_{2}(\mathrm{~g})$ is allowed to react with 1.00 mol of $\mathrm{I}_{2}(\mathrm{~g})$ in a $10.0 \mathrm{dm}^{3}$ closed-rigid-reaction vessel at 800 K , what are the concentrations of $\mathrm{H}_{2}(\mathrm{~g}), \mathrm{I}_{2}(\mathrm{~g})$, and $\mathrm{HI}(\mathrm{g})$ at equilibrium? What is the composition of the equilibrium mixture in moles?

## Answer

The initial concentrations are $\left[\mathrm{H}_{2}(\mathrm{~g})\right]=\left[\mathrm{I}_{2}(\mathrm{~g})\right]=1.00 \mathrm{~mol} / 10.0 \mathrm{dm}^{3}$

$$
=0.10 \mathrm{~mol} \mathrm{dm}^{-3} .
$$

For convenience, define an unknown, $x$, as the concentration $\left(\mathrm{mol} \mathrm{dm}^{-3}\right)$ of $\mathrm{H}_{2}(\mathrm{~g})$ that reacts. According to the balanced equation for the reaction, $x \mathrm{~mol} \mathrm{dm}^{-3}$ of $\mathrm{H}_{2}(\mathrm{~g})$ reacts with $x \mathrm{~mol} \mathrm{dm}^{-3}$ of $\mathrm{I}_{2}(\mathrm{~g})$ to give $2 x \mathrm{~mol} \mathrm{dm}^{-3}$ of $\mathrm{HI}(\mathrm{g})$. This reduces the initial concentrations of $\mathrm{H}_{2}(\mathrm{~g})$ and $\mathrm{I}_{2}(\mathrm{~g})$ from $0.10 \mathrm{~mol} \mathrm{dm}^{-3}$ to $(0.10-x) \mathrm{mol} \mathrm{dm}^{-3}$ at equilibrium.

These can be summarized in a table under the balanced equation:

|  | $\mathrm{H}_{2}(\mathrm{~g})$ | + | $\mathrm{I}_{2}(\mathrm{~g})$ | $\rightleftharpoons$ | $2 \mathrm{HI}(\mathrm{g})$ |
| :--- | :--- | :--- | :--- | :--- | :--- |
| Initial $/ \mathrm{mol} \mathrm{dm}$ |  |  |  |  |  |
|  | 0.1 | 0.1 | 0 |  |  |
| Change $/ \mathrm{mol} \mathrm{dm}^{-3}$ | $-x$ | $-x$ |  | $+2 x$ |  |
| Equilibrium $/ \mathrm{mol} \mathrm{dm}^{-3}$ | $(0.10-x)$ | $(0.10-x)$ |  | $2 x$ |  |

The equilibrium constant, $K_{\mathrm{C}}=\frac{[\mathrm{HI}(\mathrm{g})]^{2}}{\left[\mathrm{H}_{2}(\mathrm{~g})\right]\left[\mathrm{I}_{2}(\mathrm{~g})\right]}$
Substituting the values; $\quad 64.0=\frac{(2 x)^{2}}{(0.10-x)(0.10-x)}=\frac{(2 x)^{2}}{(0.10-x)^{2}} \quad=\left[\frac{2 x}{0.10-x)}\right]^{2}$
Taking square roots of both sides: $\quad \pm 8.0=\frac{2 x}{(0.10-x)}$
Taking + 8.0; $\quad 0.80-8 x=2 x$ $x=0.08 \mathrm{~mol} \mathrm{dm}^{-3}$
(If we take $-8.0=\frac{2 x}{(0.10-x)}$; we get $x=0.13 \mathrm{~mol} \mathrm{dm}^{-3}$
which is unacceptable as the initial concentration is $0.10 \mathrm{~mol} \mathrm{dm}^{-3}$ )

$$
\begin{aligned}
\therefore\left[\mathrm{H}_{2}(\mathrm{~g})\right]=\left[\mathrm{I}_{2}(\mathrm{~g})\right] & =0.02 \mathrm{~mol} \mathrm{dm}^{-3} \text { and }[\mathrm{HI}(\mathrm{~g})] \\
& =0.16 \mathrm{~mol} \mathrm{dm}^{-3}
\end{aligned}
$$

$\therefore$ The composition in moles: $\mathrm{H}_{2}(\mathrm{~g})=\mathrm{I}_{2}(\mathrm{~g})=0.02 \mathrm{~mol} \mathrm{dm}^{-3} \times 10.0 \mathrm{dm}^{3}$

$$
=0.2 \mathrm{~mol}
$$

$$
\text { And } \mathrm{HI}(\mathrm{~g})=1.6 \mathrm{~mol}
$$

## Example 2.8

For the same reaction and temperature as in the previous example, suppose that the initial concentrations of $\mathrm{H}_{2}(\mathrm{~g}), \mathrm{I}_{2}(\mathrm{~g})$, and $\mathrm{HI}_{(\mathrm{g})}$ are $0.006 \mathrm{~mol} \mathrm{dm}^{-3}, 0.004 \mathrm{~mol} \mathrm{dm}^{-3}$, and $0.02 \mathrm{~mol} \mathrm{dm}^{-3}$ respectively. Calculate the concentrations of these species at equilibrium.

## Answer

As the initial concentrations do not correspond to the equilibrium concentrations, let $x$ be the depletion in concentration ( $\mathrm{mol} \mathrm{dm}^{-3}$ ) of $\mathrm{H}_{2}(\mathrm{~g})$ and $\mathrm{I}_{2}(\mathrm{~g})$, at equilibrium. From the stoichiometry of the reaction it follows that the increase in concentration for HI must be $2 x$.

|  | $\mathrm{H}_{2}(\mathrm{~g})$ | + | $\mathrm{I}_{2}(\mathrm{~g})$ | $\rightleftharpoons$ |
| :--- | :--- | :--- | :--- | :--- |
| Initial $/ \mathrm{mol} \mathrm{dm}^{-3}$ | 0.006 | 0.004 | 0.02 |  |
| Change $/ \mathrm{mol} \mathrm{dm}$ |  |  |  |  |
| E |  | $-x$ | $-x$ |  |
| Equilibrium $/ \mathrm{mol} \mathrm{dm}^{-3}$ | $(0.006-x)$ | $(0.004-x)$ |  | $(0.02+2 x)$ |

## G.C.E. (A/L) CHEMISTRY: UNIT 12 Chemical Equilibrium

The equilibrium constant, $\quad K_{\mathrm{c}}=\frac{[\mathrm{HI}(\mathrm{g})]^{2}}{\left[\mathrm{H}_{2}(\mathrm{~g})\right]\left[\mathrm{I}_{2}(\mathrm{~g})\right]}=64=\frac{(0.02+2 x)^{2}}{(0.006-x)(0.004-x)}$
Multiplication gives us a quadratic equation;
$60 x^{2}-0.72 x+11.34 \times 10^{-4}=0$
This is of the type: $a x^{2}+b x+c=0$ and its solutions for $x$ is given by,

$$
x=\frac{-b \pm \sqrt{b^{2}-4 a c}}{2 a}
$$

By applying this to the quadratic equation we have, we get $x=0.01 \mathrm{~mol} \mathrm{dm}^{-3}$ or 0.002 $\mathrm{mol} \mathrm{dm}{ }^{-3}$. The value $0.01 \mathrm{~mol} \mathrm{dm}^{-3}$ is unacceptable as the equilibrium concentration cannot be higher than the initial concentration. Therefore the accepted value of $x$ is $0.002 \mathrm{~mol} \mathrm{dm}^{-3}$.

Now the equilibrium concentrations are:
$\left[\mathrm{H}_{2}(\mathrm{~g})\right]=(0.006-0.002)=0.004 \mathrm{~mol} \mathrm{dm}^{-3}$
$\left[\mathrm{I}_{2}(\mathrm{~g})\right]=(0.004-0.002)=0.002 \mathrm{~mol} \mathrm{dm}^{-3}$
$[\mathrm{HI}(\mathrm{g})]=(0.02+0.004)=0.024 \mathrm{~mol} \mathrm{dm}^{-3}$

Figure 2.9 Chemical equilibrium in the reaction $\mathrm{H}_{2}(\mathrm{~g})+\mathrm{I}_{2}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{HI}(\mathrm{g})$ can be attained from either direction. This explains that the reaction can start from either side (right and left) with a mixture of $\mathrm{H}_{2}(\mathrm{~g})$ and $\mathrm{I}_{2}(\mathrm{~g})$ or with $\mathrm{HI}(\mathrm{g})$. When it starts with $\mathrm{H}_{2}(\mathrm{~g})$ and $\mathrm{I}_{2}(\mathrm{~g})$ mixture eventually those decrease in amount while the amount of $\mathrm{HI}(\mathrm{g})$ increases. In the other way, if the reactions starts with $\mathrm{HI}(\mathrm{g})$, amounts of $\mathrm{H}_{2}(\mathrm{~g})$ and $\mathrm{I}_{2}(\mathrm{~g})$ increase with the time while the amount of $\mathrm{HI}(\mathrm{g})$ decreases.

## Example 2.9

0.15 moles of $\mathrm{N}_{2} \mathrm{O}_{4}$ gas was placed in a $1.0 \mathrm{dm}^{3}$ closed rigid reaction vessel at 400 K and allowed to attain the equilibrium $\mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{NO}_{2}(\mathrm{~g})$. The total pressure at equilibrium was found to be $9.0 \times 10^{5} \mathrm{~Pa}$. Calculate partial pressures of each and hence $\boldsymbol{K}_{\boldsymbol{p}}$ and $\boldsymbol{K}_{\boldsymbol{C}}$ at equilibrium.

## Answer

Assuming ideal behaviour for $\mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g})$;
$P V=n R T$
$P_{\mathrm{N}_{2} \mathrm{O}_{4}}=0.15 \mathrm{~mol} \times 8.314 \mathrm{~J} \mathrm{~mol}^{-1} \mathrm{~K}^{-1} \times 400 \mathrm{~K} \approx 5.0 \times 10^{5} \mathrm{~Pa}$
Therefore, initial pressure $=4.98 \times 10^{5} \mathrm{~Pa}$
Consider the reaction,

## Example 2.10

The reduction of iron(II) oxide by carbon monoxide gives iron metal and carbon dioxide. The equilibrium constant $K_{\mathrm{p}}$ for the reaction at 1000 K is 0.25 .

$$
\mathrm{FeO}(\mathrm{~s})+\mathrm{CO}(\mathrm{~g}) \rightleftharpoons \mathrm{Fe}(\mathrm{~s})+\mathrm{CO}_{2}(\mathrm{~g})
$$

What are the equilibrium partial pressures of $\mathrm{CO}(\mathrm{g})$ and $\mathrm{CO}_{2}(\mathrm{~g})$ at 1000 K if the initial partial pressures are $P_{\mathrm{CO}(\mathrm{g})}=1.0 \times 10^{5} \mathrm{~Pa}$ and $P_{\mathrm{CO}_{2}(\mathrm{~g})}=0.50 \times 10^{5} \mathrm{~Pa}$. Comment on the value calculated.

## Answer

We can calculate equilibrium partial pressures from initial partial pressures and In the same way that we calculate equilibrium concentrations from initial concentrations and substitute partial pressures for concentrations.

$$
\begin{array}{rl}
\mathrm{FeO}(\mathrm{~s})+\mathrm{CO}(\mathrm{~g}) \rightleftharpoons \mathrm{Fe}(\mathrm{~s})+ & \mathrm{CO}_{2}(\mathrm{~g}) \\
1.0 \times 10^{5} & 0.50 \times 10^{5} \\
-x & \\
& +x \\
\left(1.0 \times 10^{5}-x\right) & \left(0.50 \times 10^{5}+x\right)
\end{array}
$$

Initia pressure/ Pa
Change pressure/ Pa
Equilibrium pressure ( Pa )

$$
\begin{gathered}
K_{P}=\frac{\left(P_{\mathrm{CO}_{2}(\mathrm{~g})}\right)}{\left(P_{\mathrm{CO}(\mathrm{~g})}\right)}=0.25=\frac{\left(0.50 \times 10^{5}+x\right)}{\left(1.0 \times 10^{5}-x\right)} \\
0.25 \times 10^{5}-0.25 x=0.50 \times 10^{5}+x \\
x=-0.20 \times 10^{5} \mathrm{~Pa} \\
\therefore P_{\mathrm{CO}(\mathrm{~g})}=1.20 \times 10^{5} \mathrm{~Pa} \\
P_{\mathrm{CO}_{2}(\mathrm{~g})}=0.30 \times 10^{5} \mathrm{~Pa}
\end{gathered}
$$

A negative value for x means that the reaction goes from products to reactants to reach equilibrium. This makes sense because the initial reaction quotient, $Q_{\mathrm{p}}=\frac{0.5}{1.0}=0.5>K_{\mathrm{p}}$ : is greater than the equilibrium constant, i.e. the net reaction always goes from products to reactants (right to left).

We can confirm this by the re-calculation of $K_{\mathrm{P}}$ using the derived values for $P_{\mathrm{CO}(\mathrm{g})}$ and $P_{\mathrm{CO}_{2}(\mathrm{~g})}$. We get $K_{\mathrm{p}}=\frac{0.30 \times 10^{5} \mathrm{~Pa}}{1.20 \times 10^{5} \mathrm{~Pa}}=0.25$. So that the above given reaction proceeds to the left.

## Example 2.11

The chemical equation for the reaction of hydrogen with ethylene $\left(\mathrm{C}_{2} \mathrm{H}_{4}\right)$ in the presence of a catalyst to give ethane $\left(\mathrm{C}_{2} \mathrm{H}_{6}\right)$ is:
$\mathrm{H}_{2}(\mathrm{~g})+\mathrm{C}_{2} \mathrm{H}_{4}(\mathrm{~g}) \rightleftharpoons \mathrm{C}_{2} \mathrm{H}_{6}(\mathrm{~g})$.
Equilibrium constant of the reaction $K_{\mathrm{c}}=9.6 \times 10^{18}$ at $25^{\circ} \mathrm{C}$. If a mixture of 0.200 $\mathrm{mol} \mathrm{dm}{ }^{-3} \mathrm{H}_{2}(\mathrm{~g})$ and $0.155 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{C}_{2} \mathrm{H}_{4}(\mathrm{~g})$ is maintained at $25^{\circ} \mathrm{C}$ in the presence of a powdered nickel catalyst, what is the equilibrium concentration of each substance in the mixture?

## Answer

Very large value of $K_{\mathrm{c}}$ shows that the reaction goes to completion. i.e. As the amount of $\mathrm{H}_{2}(\mathrm{~g})\left(0.200 \mathrm{~mol} \mathrm{dm}^{-3}\right)$ is higher than the amount of $\mathrm{C}_{2} \mathrm{H}_{4}(\mathrm{~g})\left(0.155 \mathrm{~mol} \mathrm{dm}^{-3}\right)$, it is clear that all the $\mathrm{C}_{2} \mathrm{H}_{4}(\mathrm{~g})$ is consumed to produce $0.155 \mathrm{~mol} \mathrm{dm}^{-3}$ of $\mathrm{C}_{2} \mathrm{H}_{6}(\mathrm{~g})$. Therefore the remaining amount of $\mathrm{H}_{2}(\mathrm{~g})$ is $(0.200-0.155) \mathrm{mol} \mathrm{dm}^{-3}=0.045 \mathrm{~mol} \mathrm{dm}^{-}$ ${ }^{3}$. As the $K_{\mathrm{c}}$ of the forward reaction is very large, the equilibrium constant for the reverse reaction should be very small. On this basis we can consider that the reverse reaction occurs in which the amount of $\mathrm{C}_{2} \mathrm{H}_{6}(\mathrm{~g})$ consumed is $x$ and the following equilibrium is built-up.

We can check and confirm the answer by substituting the values in $K_{\mathrm{c}}$ expression.

$$
K_{\mathrm{c}}=\frac{\left[\mathrm{C}_{2} \mathrm{H}_{6}(\mathrm{~g})\right]}{\left[\mathrm{H}_{2}(\mathrm{~g})\right]\left[\mathrm{C}_{2} \mathrm{H}_{4}(\mathrm{~g})\right]}=\frac{0.155}{0.045\left(3.6 \times 10^{-19}\right)}=9.6 \times 10^{18}
$$

i. e. the assumptions made are correct.

### 2.1.12 Factors affecting the equilibrium

From the above discussions we now know that the chemical equilibrium is a balance between forward and reverse reactions at a constant temperature in a closed rigid system. Changes in experimental conditions may disturb the balance and shift the equilibrium position so that more or less of the desired product is formed. When we say that an equilibrium position shifts to the right, for example, we mean that the net reaction is now from left to right or vice-versa. Variables that can be controlled experimentally are concentration, pressure, volume, and temperature. Here, we will examine how each of these variables affects a reacting system at equilibrium. The qualitative effect of the above

## G.C.E. (A/L) CHEMISTRY: UNIT 12 Chemical Equilibrium

variables on the composition of an equilibrium mixture can be predicted using a principle first described by the French chemist Henri-Louis Le Chātelier.

## Le Chätelier's principle:

Change in any of the factors that determine the equilibrium conditions of a system will cause the system to change in such a manner so as to reduce or to counteract the effect of the change.

This is applicable to all physical and chemical equilibria.

## Effect of concentration change

In general, when equilibrium is disturbed by the addition/removal of any reactant/ product, Le Chatelier's principle predicts that:

- The concentration stress of an added reactant/product is relieved by net reaction in the direction that consumes the added substance.
- The concentration stress of a removed reactant/product is relieved by net reaction in the direction that replenishes the removed substance.
or in other words:
"When the concentration of any of the reactants or products in a reaction at equilibrium is changed, the composition of the equilibrium mixture changes so as to minimize the effect of concentration change".

Let us consider the reaction,

$$
\mathrm{H}_{2}(\mathrm{~g})+\mathrm{I}_{2}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{HI}(\mathrm{~g})
$$

If $\mathrm{H}_{2(\mathrm{~g})}$ is added to the reaction mixture at equilibrium, then the equilibrium of the reaction is disturbed. In order to restore it, the reaction proceeds in a direction wherein $\mathrm{H}_{2}(\mathrm{~g})$ is consumed, i.e., more of $\mathrm{H}_{2}(\mathrm{~g})$ and $\mathrm{I}_{2}(\mathrm{~g})$ react to form $2 \mathrm{HI}(\mathrm{g})$ and finally the equilibrium shifts to right (forward). This is in accordance with the Le Chātelier's principle which implies that in case of addition of a reactant/product, a new equilibrium will be set up in which the concentration of the reactant/product should be less than what it was after the addition but more than what it was in the original mixture. Figure 2.10 illustrates the system.

Figure 2.10 Effect of addition of $\mathrm{H}_{2}$ on the change of concentration for the reactants and products in the reaction, $\mathrm{H}_{2}(\mathrm{~g})+\mathrm{I}_{2}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{HI}(\mathrm{g})$

This behaviour can be explained in terms of the reaction quotient, $\boldsymbol{Q}_{\mathbf{c}}$

$$
Q_{c}=\frac{[\mathrm{HI}(\mathrm{~g})]^{2}}{\left[\mathrm{H}_{2}(\mathrm{~g})\right]\left[\mathrm{I}_{2}(\mathrm{~g})\right]}
$$

Addition of hydrogen at equilibrium results in the increase in the magnitude of the denominator which in turn decreases the value of $Q_{\mathrm{c}}$ below $K_{\mathrm{c}}$. Thus, in order to release this stress, more $\mathrm{H}_{2}(\mathrm{~g})$ will be consumed making the forward reaction predominant. Therefore, the system will readjust with time making the forward reaction to move forward to attain a new equilibrium. Similarly, we can understand that the removal of a product also boosts the forward reaction and increases the concentration of the products.

Another simple system that can be tested experimentally in the laboratory is the equilibrium in $\operatorname{Iron}(\mathrm{III})$-thiocyanate system. $\left[\mathrm{Fe}(\mathrm{SCN})_{3}\right]$ dissolves readily in water to give a red solution. The red colour is due to the presence of hydrated $[\mathrm{FeSCN}]^{2+}$ ion. The equilibrium between undissociated $[\mathrm{FeSCN}]^{2+}$ and the $\mathrm{Fe}^{3+}$ and $\mathrm{SCN}^{-}$ions is given by

$$
\begin{gathered}
{[\mathrm{FeSCN}]^{2+}(\mathrm{aq})} \\
\text { red }
\end{gathered} \underset{\text { pale yellow }}{\mathrm{Fe}^{3+}(\mathrm{aq})}+\underset{\text { colourless }}{\mathrm{SCN}^{-}(\mathrm{aq})}
$$

Once we add some sodium thiocyanate ( NaSCN ) to this solution, the stress applied to the equilibrium system increases the concentration of $\mathrm{SCN}^{-}(\mathrm{aq})$. To relieve this stress, some $\mathrm{Fe}^{3+}(\mathrm{aq})$ ions react with the added $\mathrm{SCN}^{-}(\mathrm{aq})$ ions, and the equilibrium shifts from right to left by deepening the red colour of the solution. Similarly, if we add $\mathrm{Fe}^{3+}(\mathrm{aq})$ ions to the original solution, the red colour would also deepen because the additional $\mathrm{Fe}^{3+}(\mathrm{aq})$ ions shift the equilibrium from right to left.

Further, if we write the above equilibrium as;
$\underset{\substack{\mathrm{Fe}^{3+}(\mathrm{aq}) \\ \text { pale yellow }}}{+} \underset{\text { colourless }}{\mathrm{SCN}^{-}(\mathrm{aq})} \rightleftharpoons \underset{\text { red }}{[\mathrm{FeSCN}]^{2+}(\mathrm{aq})}$

This equilibrium can be shifted in either forward or reverse directions depending on our choice of adding a reactant or a product. The equilibrium can be shifted in the opposite direction by adding reagents that remove $\mathrm{Fe}^{3+}(\mathrm{aq})$ or $\mathrm{SCN}^{-}(\mathrm{aq})$ ions. For example, oxalic acid $\left(\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}\right)$, reacts with $\mathrm{Fe}^{3+}(\mathrm{aq})$ ions to form the stable complex ion $\left[\mathrm{Fe}\left(\mathrm{C}_{2} \mathrm{O}_{4}\right)_{3}\right]^{3-}$, thus decreasing the concentration of free $\mathrm{Fe}^{3+}(\mathrm{aq})$. In accordance with the Le Chatelier's principle, the concentration stress of removed $\mathrm{Fe}^{3+}(\mathrm{aq})$ is relieved by dissociation of $[\mathrm{Fe}(\mathrm{SCN})]^{2+}$ to replenish the $\mathrm{Fe}^{3+}(\mathrm{aq})$ ions. Because the concentration of $[\mathrm{Fe}(\mathrm{SCN})]^{2+}$ decreases, the intensity of red color decreases.

This effect can be explained by the reactions shown below.

$$
\begin{gathered}
3 \mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}(\mathrm{aq})+\mathrm{Fe}^{3+}(\mathrm{aq}) \rightarrow\left[\mathrm{Fe}\left(\mathrm{C}_{2} \mathrm{O}_{4}\right)_{3}\right]^{3-}(\mathrm{aq})+6 \mathrm{H}^{+}(\mathrm{aq}) \\
\text { and } \\
{[\mathrm{FeNCS}]^{2+}(\mathrm{aq}) \rightleftharpoons \mathrm{Fe}^{3+}(\mathrm{aq})+\mathrm{SCN}^{-}(\mathrm{aq})}
\end{gathered}
$$

Addition of aq. $\mathrm{HgCl}_{2}$ also decreases red colour because $\mathrm{Hg}^{2+}(\mathrm{aq})$ reacts with $\mathrm{SCN}^{-}(\mathrm{aq})$ ions to form the stable complex ion $\left[\mathrm{Hg}(\mathrm{SCN})_{4}\right]^{2-}$. Removal of free $\mathrm{SCN}^{-}(\mathrm{aq})$ shifts the equilibrium from right to left to replenish $\mathrm{SCN}^{-}(\mathrm{aq})$ ions. Addition of potassium KSCN on the other hand increases the colour intensity of the solution as it shift the equilibrium to right.

$$
\begin{aligned}
\mathrm{HgCl}_{2}(\mathrm{aq})+4 \mathrm{SCN}^{-}(\mathrm{aq}) \rightarrow & {\left[\mathrm{Hg}(\mathrm{SCN})_{4}\right]^{2-}(\mathrm{aq})+2 \mathrm{Cl}^{-}(\mathrm{aq}) } \\
& \text { and } \\
{\left[\mathrm{FeNCS}^{2+}(\mathrm{aq})\right.} & \rightleftharpoons \mathrm{Fe}^{3+}(\mathrm{aq})+\mathrm{SCN}^{-}(\mathrm{aq})
\end{aligned}
$$

## Example:

Let's consider the following equilibrium system in the Haber process for the synthesis of ammonia:

$$
\mathrm{N}_{2}(\mathrm{~g})+3 \mathrm{H}_{2}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{NH}_{3}(\mathrm{~g}) \quad K_{C}=0.291 \text { at } 700 \mathrm{~K}
$$

Suppose we have an equilibrium mixture of $0.50 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{~N}_{2}(\mathrm{~g}), 3.00 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{H}_{2}(\mathrm{~g})$, and $1.98 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{NH}_{3}(\mathrm{~g})$ at 700 K and that we disturb the equilibrium by increasing the $\mathrm{N}_{2}(\mathrm{~g})$ concentration to $1.50 \mathrm{~mol} \mathrm{dm}^{-3}$. Le Châtelier's principle tells us that the reaction will occur to relieve the stress of the increased concentration of $\mathrm{N}_{2}(\mathrm{~g})$ by converting some of the $\mathrm{N}_{2}(\mathrm{~g})$ to $\mathrm{NH}_{3}(\mathrm{~g})$. It is clear that the number of gaseous molecules decreases in the forward direction allowing the release in the stress. i.e. as the $\mathrm{N}_{2}(\mathrm{~g})$ concentration decreases, the $\mathrm{H}_{2}(\mathrm{~g})$ concentration must also decrease and the $\mathrm{NH}_{3}(\mathrm{~g})$ concentration must increase in accordance with the stoichiometry of the balanced equation.

These changes can be explained by the following Figure 2.11.

Figure 2.11 Effect of addition of $\mathrm{N}_{2}$ on the change of concentration for the reactants and products in the reaction, $\mathrm{N}_{2}(\mathrm{~g})+3 \mathrm{H}_{2}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{NH}_{3}(\mathrm{~g})$

Now we can understand that once the rules of Le Châtelier's principle are applied to the equilibrium, the yield of ammonia is increased by an increase in the $\mathrm{N}_{2}(\mathrm{~g})$ or $\mathrm{H}_{2}(\mathrm{~g})$ concentration or by a decrease in the $\mathrm{NH}_{3}(\mathrm{~g})$ concentration and the sketch below gives us a kind of summary on the effect on the equilibrium position.

Red : Shifts the equilibrium to right
Blue : Shifts the equilibrium to left

Sketch 1 An increase in the $\mathrm{N}_{2}(\mathrm{~g})$ or $\mathrm{H}_{2}(\mathrm{~g})$ concentration or a decrease in the $\mathrm{NH}_{3}(\mathrm{~g})$ concentration shifts the equilibrium from left to right. A decrease in the $\mathrm{N}_{2}(\mathrm{~g})$ or $\mathrm{H}_{2}(\mathrm{~g})$ concentration or an increase in the $\mathrm{NH}_{3}(\mathrm{~g})$ concentration shifts the equilibrium from right to left.

Though Le Châtelier's principle gives us to predict changes in the composition of an equilibrium mixture with the applying stress, it does not explain why those changes occur. However, we can understand the effect by considering the reaction quotient $\boldsymbol{Q}_{\mathbf{c}}$. For the initial equilibrium mixture of $0.50 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{~N}_{2}(\mathrm{~g}), 3.00 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{H}_{2}(\mathrm{~g})$, and $1.98 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{NH}_{3}(\mathrm{~g})$ at $700 \mathrm{~K}, \boldsymbol{Q}_{\mathbf{c}}$ equals the equilibrium constant $\boldsymbol{K}_{\mathbf{c}}$ ( 0.291 ) because the system is at equilibrium:

$$
Q_{\mathrm{c}}=\frac{\left[\mathrm{NH}_{3}(\mathrm{~g})\right]^{2}}{\left.\left[\mathrm{~N}_{2}(\mathrm{~g})\right]\left[\mathrm{H}_{2(\mathrm{~g})}\right]^{3}\right]}=\frac{[1.98]^{2}}{\left.[0.5][3.0]^{3}\right]}=0.29=K_{\mathrm{c}}
$$

When we disturb the equilibrium by increasing the $\mathrm{N}_{2}(\mathrm{~g})$ concentration to $1.50 \mathrm{~mol} \mathrm{dm}^{-3}$, the denominator of the equilibrium constant expression increases and $Q_{\mathrm{c}}$ decreases to a value less than $K_{\mathrm{c}}$ :

$$
Q_{\mathrm{c}}=\frac{\left[\mathrm{NH}_{3}(\mathrm{~g})\right]^{2}}{\left.\left[\mathrm{~N}_{2}(\mathrm{~g})\right]\left[\mathrm{H}_{2}(\mathrm{~g})\right]^{3}\right]}=\frac{[1.98]^{2}}{\left.[1.5][3.0]^{3}\right]}=0.0968<K_{\mathrm{c}}
$$

For the system to move to a new state of equilibrium, $Q_{c}$ must increase; that is, the numerator of the equilibrium constant expression must increase and the denominator must decrease. This implies that the net conversion of $\mathrm{N}_{2}(\mathrm{~g})$ and $\mathrm{H}_{2}(\mathrm{~g})$ to $\mathrm{NH}_{3}(\mathrm{~g})$ occurs just as predicted by Le Châtelier's principle. When the new equilibrium is established as shown in Figure 2.11, the concentrations are $1.31 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{~N}_{2}(\mathrm{~g}), 2.43 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{H}_{2}(\mathrm{~g})$, and $2.36 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{NH}_{3}(\mathrm{~g})$, and $Q_{\mathrm{c}}$ again equals $K_{\mathrm{c}}$ :

$$
Q_{c}=\frac{[2.36]^{2}}{\left.[1.31][2.43]^{3}\right]}=0.29=K_{\mathrm{c}}
$$

## Example:

## Applying Le Châtelier's principle to solid $\rightleftharpoons$ gas systems:

The reaction of iron(III) oxide with carbon monoxide occurs in a blast furnace when iron ore is reduced to iron metal:

$$
\mathrm{Fe}_{2} \mathrm{O}_{3}(\mathrm{~s})+3 \mathrm{CO}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{Fe}(\mathrm{l})+3 \mathrm{CO}_{2}(\mathrm{~g})
$$

Let's use Le Châtelier's principle to predict the direction of the net reaction when an equilibrium mixture is disturbed by:
(a) Adding $\mathrm{Fe}_{2} \mathrm{O}_{3}$
(b) Removing $\mathrm{CO}_{2}$
(c) Removing CO; while accounting for the change using the reaction quotient $Q c$.
(a) Because $\mathrm{Fe}_{2} \mathrm{O}_{3}$ is a pure solid, its concentration is equal to 1 and does not change when more $\mathrm{Fe}_{2} \mathrm{O}_{3}$ is added. Therefore, there is no concentration stress and the original equilibrium is undisturbed.
(b) Le Châtelier's principle predicts that the concentration stress of $\mathrm{CO}_{2}$ removed will be relieved by net reaction shift from reactants to products to replenish $\mathrm{CO}_{2}$.
(c) Le Châtelier's principle predicts that the concentration stress of CO removed will be relieved by net reaction shift from products to reactants to replenish CO. The reaction quotient is;

$$
Q_{\mathrm{c}}=\frac{\left[\mathrm{CO}_{2}(\mathrm{~g})\right]^{3}}{[\mathrm{CO}(\mathrm{~g})]^{3}}
$$

When the equilibrium is disturbed by reducing [CO], $Q_{\mathrm{c}}$ increases, so that $Q_{\mathrm{c}}>K_{\mathrm{c}}$. For the system to move to a new state of equilibrium, $Q_{c}$ must decrease; that is, $\left[\mathrm{CO}_{2}\right]$ must decrease and $[\mathrm{CO}]$ must increase. Therefore, the net reaction goes from products to reactants, as predicted by Le Châtelier's principle.

## G.C.E. (A/L) CHEMISTRY: UNIT 12 Chemical Equilibrium

## Example 1:

Lead carbonate decomposes to lead oxide and carbon dioxide according to the following equation:

$$
\mathrm{PbCO}_{3}(\mathrm{~s}) \rightleftharpoons \mathrm{PbO}(\mathrm{~s})+\mathrm{CO}_{2}(\mathrm{~g})
$$

Because $\mathrm{PbCO}_{3}$ and PbO are solids, the equilibrium constant is simply $K=\left[\mathrm{CO}_{2}(\mathrm{~g})\right]$. At a given temperature, therefore, any system that contains solid $\mathrm{PbCO}_{3}$ and solid PbO will have exactly the same concentration of $\mathrm{CO}_{2}(\mathrm{~g})$ at equilibrium, regardless of the ratio or the amounts of the solids present. This can be understand by Figure 2.12, which shows a plot of $\left[\mathrm{CO}_{2}(\mathrm{~g})\right]$ versus the amount of solid $\mathrm{PbCO}_{3}$ added. Initially, the added $\mathrm{PbCO}_{3}$ decomposes completely to $\mathrm{CO}_{2}(\mathrm{~g})$ because the amount of $\mathrm{PbCO}_{3}$ is not sufficient to give a $\mathrm{CO}_{2}(\mathrm{~g})$ concentration equal to $K$. Thus the left portion of the graph represents a system that is not at equilibrium because it contains only $\mathrm{CO}_{2}(\mathrm{~g})$ and $\mathrm{PbO}(\mathrm{s})$. In contrast, when just enough $\mathrm{PbCO}_{3}$ has been added to give $\left[\mathrm{CO}_{2}(\mathrm{~g})\right]=K$, the system has reached equilibrium, and adding more $\mathrm{PbCO}_{3}$ has no effect on the $\mathrm{CO}_{2}(\mathrm{~g})$ concentration: so the graph is a horizontal line. Thus any $\mathrm{CO}_{2}(\mathrm{~g})$ concentration that is not on the horizontal line represents a non-equilibrium state, and the system will adjust its composition to achieve equilibrium, provided enough $\mathrm{PbCO}_{3}$ and PbO are present. For example, the point labelled as $\mathbf{A}$ in Figure 2.12, the concentration of $\mathrm{CO}_{2}(\mathrm{~g})$ lies above the horizontal line, so it corresponds to a $\left[\mathrm{CO}_{2}(\mathrm{~g})\right]$ that is greater than the equilibrium concentration of $\mathrm{CO}_{2}(\mathrm{~g})(Q>K)$. To reach equilibrium, the system must decrease $\left[\mathrm{CO}_{2}(\mathrm{~g})\right]$, which it can do only by reacting $\mathrm{CO}_{2}(\mathrm{~g})$ with solid PbO to form solid $\mathrm{PbCO}_{3}$. Thus the reaction will proceed to the left side, until $\left[\mathrm{CO}_{2}(\mathrm{~g})\right]=K$. Conversely, the point labelled as $\mathbf{B}$ in the figure, the concentration of gaseous $\mathrm{CO}_{2}(\mathrm{~g})$ lies below the horizontal line, so it corresponds to a $\left[\mathrm{CO}_{2}(\mathrm{~g})\right]$ that is less than the equilibrium concentration of $\mathrm{CO}_{2}(\mathrm{~g})$ ( $Q<K$ ). To reach equilibrium, the system must increase $\left[\mathrm{CO}_{2}(\mathrm{~g})\right]$, which it can do only by decomposing solid $\mathrm{PbCO}_{3}$ to form $\mathrm{CO}_{2}(\mathrm{~g})$ and solid PbO . The reaction will therefore proceed to the right as written, until $\left[\mathrm{CO}_{2}(\mathrm{~g})\right]=K$.

Figure 2.12 Initially the concentration of $\mathrm{CO}_{2}(\mathrm{~g})$ increases linearly with the amount of solid $\mathrm{PbCO}_{3}$ added, as $\mathrm{PbCO}_{3}$ decomposes to $\mathrm{CO}_{2}(\mathrm{~g})$ and solid PbO . Once the $\mathrm{CO}_{2}(\mathrm{~g})$ concentration reaches the value that corresponds to the equilibrium concentration, however, adding more solid $\mathrm{PbCO}_{3}$ has no effect on $\left[\mathrm{CO}_{2}(\mathrm{~g})\right]$, as long as the temperature remains constant.

## Example 2:

The reduction of cadmium oxide by hydrogen giving metallic cadmium and water vapour exhibits a manner which further gives us much understanding about the Le Châtelier's principle.

$$
\mathrm{CdO}(\mathrm{~s})+\mathrm{H}_{2}(\mathrm{~g}) \rightleftharpoons \mathrm{Cd}(\mathrm{~s})+\mathrm{H}_{2} \mathrm{O}(\mathrm{~g})
$$

Equilibrium constant $\boldsymbol{K}_{\mathbf{c}}$ is $\left[\mathrm{H}_{2} \mathrm{O}(\mathrm{g})\right] /\left[\mathrm{H}_{2}(\mathrm{~g})\right]$. For example, if $\left[\mathrm{H}_{2} \mathrm{O}(\mathrm{g})\right]$ is doubled at equilibrium, then $\left[\mathrm{H}_{2}(\mathrm{~g})\right]$ must also be doubled for the system to remain at equilibrium. A plot of $\left[\mathrm{H}_{2} \mathrm{O}(\mathrm{g})\right]$ versus $\left[\mathrm{H}_{2}(\mathrm{~g})\right]$ at equilibrium is a straight line with a slope of $\boldsymbol{K}_{\mathbf{c}}$. Again, only those pairs of concentrations of $\mathrm{H}_{2} \mathrm{O}(\mathrm{g})$ and $\mathrm{H}_{2}(\mathrm{~g})$ that lie on the line correspond to equilibrium states. Any point representing a pair of concentrations that does not lie on the line corresponds to a non-equilibrium state. In such cases, the reaction will proceed in whichever direction causes the composition of the system to move toward the equilibrium line. For example, point A in Figure 2.13 lies below the line, indicating that the $\left[\mathrm{H}_{2} \mathrm{O}(\mathrm{g})\right] /\left[\mathrm{H}_{2}(\mathrm{~g})\right]$ ratio is less than the ratio of an equilibrium mixture $(Q<K)$. Thus the reaction will proceed to the right as written, consuming $\mathrm{H}_{2}(\mathrm{~g})$ and producing $\mathrm{H}_{2} \mathrm{O}(\mathrm{g})$, which causes the concentration ratio to move up and to the left toward the equilibrium line. Conversely, point B in Figure 2.13 lies above the line, indicating that the $\left[\mathrm{H}_{2} \mathrm{O}(\mathrm{g})\right] /\left[\mathrm{H}_{2}(\mathrm{~g})\right]$ ratio is greater than the ratio of an equilibrium mixture $(Q>K)$. Thus the reaction will proceed to the left as written, consuming $\mathrm{H}_{2} \mathrm{O}(\mathrm{g})$ and producing $\mathrm{H}_{2}(\mathrm{~g})$, which causes the concentration ratio to move down and to the right toward the equilibrium line.

Figure 2.13 For any equilibrium concentration of $\mathrm{H}_{2} \mathrm{O}(\mathrm{g})$, there is only one equilibrium concentration of $\mathrm{H}_{2}(\mathrm{~g})$. Because the magnitudes of the two concentrations are directly proportional, a large $\left[\mathrm{H}_{2} \mathrm{O}(\mathrm{g})\right]$ at equilibrium requires a large $\left[\mathrm{H}_{2}(\mathrm{~g})\right]$ and vice versa. In this case, the slope of the line is equal to $\boldsymbol{K}_{\mathbf{c}}$.

## Changes in pressure and volume

To illustrate how an equilibrium mixture is affected by a change in pressure as a result of a change in the volume, let's return to the Haber synthesis of ammonia. The balanced equation for the reaction has 4 moles of gas on the reactant side of the equation and 2 moles on the product side:

$$
\mathrm{N}_{2(\mathrm{~g})}+3 \mathrm{H}_{2(\mathrm{~g})} \rightleftharpoons 2 \mathrm{NH}_{3(\mathrm{~g})} \quad K_{\mathrm{c}}=0.29 \text { at } 700 \mathrm{~K}
$$

What happens to the composition of the equilibrium mixture if we increase the pressure by decreasing the volume? (the pressure of an ideal gas is inversely proportional to the volume at constant temperature and constant number of moles of gas). According to Le Châtelier's principle, net reaction will occur in the direction that relieves the stress of the increased pressure, which means that the number of moles of gas must decrease. Therefore, we predict that the net reaction will proceed from left to right because the forward reaction converts 4 moles of gaseous reactants to 2 moles of gaseous products. In general, Le Châtelier's principle predicts that

- An increase in pressure by reducing the volume will bring about net reaction in the direction that decreases the number of moles of gas.
- A decrease in pressure by expanding the volume will bring about net reaction in the direction that increases the number of moles of gas.

To see why Le Châtelier's principle works for pressure (volume) changes, let's look again at the reaction quotient for the equilibrium mixture of $0.50 \mathrm{~mol} \mathrm{dm}{ }^{-3} \mathrm{~N}_{2}(\mathrm{~g})$, $3.00 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{H}_{2}(\mathrm{~g})$ and $1.98 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{NH}_{3}(\mathrm{~g})$ at 700 K , where $Q_{\mathrm{c}}$ equals the equilibrium constant $\boldsymbol{K}_{\mathbf{c}}(0.291)$ because the system is at equilibrium:

$$
Q_{\mathrm{c}}=\frac{\left[\mathrm{NH}_{3}(\mathrm{~g})\right]^{2}}{\left.\left[\mathrm{~N}_{2}(\mathrm{~g})\right]\left[\mathrm{H}_{2}(\mathrm{~g})\right]^{3}\right]}=\frac{[1.98]^{2}}{\left.[0.5][3.0]^{3}\right]}=0.29=K_{\mathrm{c}}
$$

If we disturb the equilibrium by reducing the volume by a factor of 2 , we not only double the total pressure, we also double the partial pressure and thus the molar concentration of each reactant and product (molarity $=n / V=P / R T$ ). Because the balanced equation has more moles of gaseous reactants than the gaseous products, the increase in the denominator of the equilibrium constant expression is greater than the increase in the numerator and the new value of $Q_{c}$ is less than the equilibrium constant.

$$
Q_{c}=\frac{\left[\mathrm{NH}_{3}(\mathrm{~g})\right]^{2}}{\left[\mathrm{~N}_{2}(\mathrm{~g})\right]\left[\mathrm{H}_{2}(\mathrm{~g})\right]}=\frac{[3.96]^{2}}{\left.[1.0][6.0]^{3}\right]}=0.073<K_{\mathrm{c}}
$$

For the system to move to a new state of equilibrium, $Q_{c}$ must increase, which means that the net reaction must go from reactants to products, as predicted by Le Châtelier's principle. In practice, the yield of ammonia in the Haber process is increased by running the reaction at high pressure, typically $130-300 \mathrm{~atm}$.

## Effect of inert gas addition

If the volume is kept constant by doing the experiment in a closed-rigid container and an inert gas such as argon is added which does not take part in the reaction, the equilibrium remains undisturbed. It is because the addition of an inert gas at constant volume does not change the partial pressures or the molar concentrations of the substances involved in the reaction. The reaction quotient changes only if the added gas is a reactant or product involved in the reaction

## Effect of temperature change

Whenever an equilibrium is disturbed by a change in the concentration, pressure or volume, the composition of the equilibrium mixture changes because the reaction quotient, $\boldsymbol{Q}_{\mathbf{c}}$ no longer equals the equilibrium constant, $\boldsymbol{K}_{\mathbf{c}}$ due to the change in equilibrium position and that does not change the value of equilibrium constant. However, when a change in temperature occurs, the value of equilibrium constant, $\boldsymbol{K}_{\mathbf{c}}$ is changed. In general, the temperature dependence of the equilibrium constant depends on the sign of $\Delta H$ for the reaction.

- The equilibrium constant for an exothermic reaction (negative $\Delta H$ ) decreases as the temperature increases.
We can write the reaction as: reactants $\rightleftharpoons$ products + heat $(\Delta H<0)$
- The equilibrium constant for an endothermic reaction (positive $\Delta H$ ) increases as the temperature increases.
We can write the reaction as : reactants + heat $\rightleftharpoons$ products $(\Delta H>0)$

According to above reactions, heat can be thought of as a product in an exothermic reaction and as a reactant in an endothermic reaction. Increasing the temperature of a system corresponds to adding heat. Le Chatelier's principle predicts that an exothermic reaction will shift to the left (toward the reactants) if the temperature of the system is increased (heat is added). Conversely, an endothermic reaction will shift to the right (toward the products) if the temperature of the system is increased. If a reaction is thermochemically neutral $\left(\Delta H_{r x n}=0\right)$, then a change in temperature will not affect the equilibrium composition.

## Example:

We can examine the effects of temperature on the dissociation of $\mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g})$ to $\mathrm{NO}_{2}(\mathrm{~g})$, for which $\Delta H=+58 \mathrm{~kJ} \mathrm{~mol}^{-1}$. This reaction can be written as follows:

$$
\begin{gathered}
58 \mathrm{~kJ}+\mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{NO}_{2}(\mathrm{~g}) \\
K_{\mathrm{c}}=\frac{\left[\mathrm{NO}_{2}(\mathrm{~g})\right]^{2}}{\left[\mathrm{~N}_{2} \mathrm{O}_{4}(\mathrm{~g})\right]}
\end{gathered}
$$

## G.C.E. (A/L) CHEMISTRY: UNIT 12 Chemical Equilibrium

Increasing the temperature (adding heat to the system) is a stress that will drive the reaction to the right. Thus increasing the temperature increases the ratio of $\mathrm{NO}_{2}(\mathrm{~g})$ to $\mathrm{N}_{2} \mathrm{O}_{4}(\mathrm{~g})$ at equilibrium, which increases equilibrium constant $\boldsymbol{K}$.

The effect of increasing the temperature on a system at equilibrium can be summarized as follows: increasing the temperature increases the magnitude of the equilibrium constant for an endothermic reaction, decreases the equilibrium constant for an exothermic reaction, and has no effect on the equilibrium constant for a thermally neutral reaction.

In summary, three types of stresses can alter the composition of an equilibrium system: adding or removing reactants or products, changing the total pressure or volume, and changing the temperature of the system. A reaction with an unfavourable equilibrium constant can be driven to completion by continually removing one of the products of the reaction. Equilibria that contain different numbers of gaseous reactant and product molecules are sensitive to changes in volume or pressure; higher pressures favour the side with fewer gaseous molecules. Removing heat from an exothermic reaction favours the formation of products, whereas removing heat from an endothermic reaction favours the formation of reactants.

## The effect of catalyst on equilibrium

The addition of a catalyst to a reaction increases the rate by providng a new, lower-energy alternative pathway for the conversion of reactants to products. Because the forward and reverse reactions pass through the same transition state, a catalyst lowers the activation energy for the forward and reverse reactions by exactly the same amount. If a reaction mixture is at equilibrium in the absence of a catalyst (that is, the forward and reverse rates are equal), it will still be at equilibrium after a catalyst is added because the forward and reverse rates, though faster, remain equal. If a reaction mixture is not at equilibrium, a catalyst accelerates the rate at which equilibrium is reached, but it does not affect the composition of the equilibrium mixture. Because a catalyst has no effect on the equilibrium concentrations, it does not appear in the balanced chemical equation or in the equilibrium constant expression (As the catalyst is not consumed in the reaction they are not considered in the overall rate equation and therefore do not affect the equilibrium of the reaction but only the rate). Even though a catalyst doesn't change the position of equilibrium it can nevertheless significantly influence the choice of optimum conditions for a reaction.

## G.C.E. (A/L) CHEMISTRY: UNIT 12 Chemical Equilibrium

Figure 2.14 Comparison of the reaction profile with and without a catalyst. The addition of a catalyst to a reaction increases the rate by providng a new, lower-energy alternative pathway as shown in (a). Also the reaction may find the similar path with multi steps and proceed via an intermediate as shown in (b).

For example, in the Haber synthesis of ammonia, because the reaction $\mathrm{N}_{2}(\mathrm{~g})+3 \mathrm{H}_{2}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{NH}_{3}(\mathrm{~g})$ is exothermic, its equilibrium constant decreases with increasing temperature, and optimum yields of $\mathrm{NH}_{3}(\mathrm{~g})$ are obtained at low temperatures. At those low temperatures, however, the rate at which equilibrium is reached is too slow for the reaction to be practical. Thus, low temperatures give good yields but slow rates, whereas high temperatures give satisfactory rates but poor yields. The answer to the dilemma is to find a catalyst. A catalyst consisting of iron mixed with certain metal oxides causes the reaction to occur at a satisfactory rate at temperatures where the equilibrium concentration of $\mathrm{NH}_{3}(\mathrm{~g})$ is reasonably favourable. The yield of $\mathrm{NH}_{3}(\mathrm{~g})$ can be improved further by running the reaction at high pressures. Typical reaction conditions for the industrial synthesis of ammonia are $400-500{ }^{\circ} \mathrm{C}$ and $130-300 \mathrm{~atm}$.

Following table summarizes the shifts in equilibrium in response to stresses imposed on an equilibrium system.

Table 2.1 Response of equilibrium system to the stresses applied

### 2.2 Ionic equilibrium in aqueous solutions

A solution can be defined as a homogeneous mixture of two or more substances. The solute is the substance present in a smaller amount or the substance that has being dissolved, and the solvent is the substance present in a larger amount. A solution may be gaseous (such as air), solid (such as an alloy), or liquid (seawater, for example). In this section we will discuss only aqueous solutions, in which the solute initially is a liquid or a solid and the solvent is water and once the solution is formed we consider the ionic form of the substances which are in equilibrium in aqueous phase.

For example, under the effect of change of concentration on the direction of equilibrium, we have earlier considered the following equilibrium which involves ions:

$$
\mathrm{Fe}^{3+}(\mathrm{aq})+\mathrm{SCN}^{-}(\mathrm{aq}) \rightleftharpoons[\mathrm{Fe}(\mathrm{SCN})]^{2+}(\mathrm{aq})
$$

There are numerous equilibria that involve ions only. It is well known that the aqueous solution of sugar does not conduct electricity. However, when common salt (sodium chloride) is added to water it conducts electricity. Also, the conductance of electricity increases with an increase in concentration of common salt. Michael Faraday classified the substances into two categories based on their ability to conduct electricity. One category of substances conduct electricity in their aqueous solutions and are called electrolytes while the other does not and are thus, referred to as nonelectrolytes. Faraday further classified electrolytes into strong and weak electrolytes. Strong electrolytes on dissolution in water are ionized almost completely, while the weak electrolytes are only partially dissociated. For example, an aqueous solution of sodium chloride is entirely composed of sodium ions and chloride ions, i.e.

$$
\mathrm{NaCl}(\mathrm{~s}) \rightarrow \mathrm{Na}^{+}(\mathrm{aq})+\mathrm{Cl}^{-}(\mathrm{aq})
$$

Acids and bases are also electrolytes. Some acids, like hydrochloric acid (HCl) and nitric acid $\left(\mathrm{HNO}_{3}\right)$, are strong electrolytes. These acids ionize completely in water; for example, when hydrogen chloride gas dissolves in water, it forms hydrated $\mathrm{H}^{+}$and $\mathrm{Cl}^{-}$ions:

$$
\mathrm{HCl}(\mathrm{aq}) \rightarrow \mathrm{H}^{+}(\mathrm{aq})+\mathrm{Cl}^{-}(\mathrm{aq})
$$

or we write the reaction as:

$$
\mathrm{HCl}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightarrow \mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})+\mathrm{Cl}^{-}(\mathrm{aq})
$$

However, that of acetic acid mainly contains unionized acetic acid molecules and only some acetate ions and protons. i.e.

$$
\mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq}) \rightleftharpoons \mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})+\mathrm{H}^{+}(\mathrm{aq})
$$

## G.C.E. (A/L) CHEMISTRY: UNIT 12 Chemical Equilibrium

or we write the reaction as:

$$
\mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})+\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})
$$

We can see that the $\rightarrow$ (single arrow) is used in the case of dissociation of HCl to show the complete or almost $100 \%$ ionization. Also we can understand that a solution of HCl does not have any free $\mathrm{HCl}(\mathrm{aq})$ molecules as they are completely dissociated to $\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})$ and $\mathrm{Cl}^{-}(\mathrm{aq})$ ions. In the case of acetic acid, $\mathrm{a} \rightleftharpoons$ (double arrow) is used to show the partial or less than $5 \%$ ionization in water and the reaction is reversible. Initially, a number of $\mathrm{CH}_{3} \mathrm{COOH}$ molecules break up into $\mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})$ and $\mathrm{H}^{+}(\mathrm{aq})$ ions. As time goes on, some of the $\mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})$ and $\mathrm{H}^{+}(\mathrm{aq})$ ions recombine into $\mathrm{CH}_{3} \mathrm{COOH}$ molecules. Eventually, a state is reached in which the acid molecules ionize as fast as the ions recombine reaching a state of chemical equilibrium. It is very important to show the physical state of each species in the system where (aq) is used to show that the species are in aqueous phase. Further, as the amount of water (solvent) is in large excess, a bare proton, $\mathrm{H}^{+}$is very reactive and cannot exist freely in aqueous solutions. Thus, it bonds to the oxygen atom of a solvent water molecule to give trigonal pyramidal hydrated proton called the hydronium ion, $\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})$. It has to be noted that the use of $\mathrm{H}^{+}(\mathrm{aq})$ and $\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})$ means the same i.e., a proton or a hydrated proton.

With the above simple explanations we can note that in weak electrolytes, equilibrium is established between ions and the unionized molecules. This type of equilibrium involving ions in aqueous solution is called ionic equilibrium. Acids, bases and salts come under the category of electrolytes and may act as either strong or weak electrolytes.

### 2.2.1 Acids, bases (and salts)

Acids, bases and salts find widespread occurrence in nature. Hydrochloric acid present in the gastric juice is secreted by the lining of our stomach in a significant amount of 1.2-1.5 L/day and is essential for digestive processes. Acetic acid is known to be the main constituent of vinegar. Lemon and orange juices contain citric and ascorbic acids. As most of the acids taste sour, the word "acid" has been derived from a latin word "acidusî meaning sour. Acids are known to turn blue litmus paper into red and liberate dihydrogen $\left(\mathrm{H}_{2}\right)$ on reacting with metals. Similarly, bases are known to turn red litmus paper blue, taste bitter and feel soapy. A common example of a base is washing soda used for washing purposes. When acids and bases are mixed in the right proportion they react with each other to give salts. Some commonly known examples of salts are sodium chloride, barium sulphate, sodium nitrate. Comparing, the ionization of hydrochloric acid with that of acetic acid in water we find that though both of them are polar covalent molecules, former is completely ionized into its constituent ions, while the latter is only partially ionized $(<5 \%)$. The extent to which ionization occurs depends upon the strength of the bond and the extent of solvation of ions produced.

## Arrhenius concept of acids and bases

According to Arrhenius theory, acids are substances that dissociates in water to give hydrogen ions $H^{+}(a q)$ and bases are substances that produce hydroxyl ions $\mathrm{OH}^{-}(\mathrm{aq})$. The ionization of an acid HX (aq) can be represented by the following equations:
$\mathrm{HX}(\mathrm{aq}) \rightarrow \mathrm{H}^{+}(\mathrm{aq})+\mathrm{X}^{-}(\mathrm{aq})$
or
$\mathrm{HX}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightarrow \mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})+\mathrm{X}^{-}(\mathrm{aq})$

Similarly, a base molecule like $\mathrm{MOH}(\mathrm{aq})$ ionizes in aqueous solution according to the equation:
$\mathrm{MOH}(\mathrm{aq}) \rightarrow \mathrm{M}^{+}(\mathrm{aq})+\mathrm{OH}^{-}(\mathrm{aq})$

The hydroxyl ion also exists in the hydrated form in the aqueous solution (eg. $\mathrm{H}_{3} \mathrm{O}_{2}^{-}{ }^{-}(\mathrm{aq})$ ). Arrhenius concept of acid and base, however, suffers from the limitation of being applicable only to aqueous solutions and also, does not account for the basicity of substances like, ammonia which do not possess a hydroxyl group.

## The Brönsted -Lowry definition of acids and bases

The Danish chemist, Johannes Brönsted and the English chemist, Thomas M. Lowry gave a more general definition of acids and bases. According to Brönsted-Lowry theory, acid is a substance that is capable of donating a hydrogen ion $\mathrm{H}^{+}$and bases are substances capable of accepting a hydrogen ion, $H^{+}$. In short, acids are proton donors and bases are proton acceptors. For example;

$$
\mathrm{HCl}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightarrow \mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})+\mathrm{Cl}^{-}(\mathrm{aq})
$$

Here we can see that the $\mathrm{HCl}(\mathrm{aq})$ molecule donates a proton to water forming $\mathrm{Cl}^{-}(\mathrm{aq})$ and $\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})$ ions. i.e. Therefore, $\mathrm{HCl}(\mathrm{aq})$ is classified as a $\mathrm{Br} \varnothing$ nsted acid because it can donate a $\mathrm{H}^{+}$ion. (We can also see that the $\mathrm{H}_{2} \mathrm{O}(1)$ molecule accepts that proton acting as a base; further insights of this nature will be explained in a latters section dealing with conjugate acid-base pairs).

$$
\mathrm{NH}_{3}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{NH}_{4}{ }^{+}(\mathrm{aq})+\mathrm{OH}^{-}(\mathrm{aq})
$$

Here we can see that the $\mathrm{NH}_{3}(\mathrm{aq})$ molecule accepts a proton from water forming $\mathrm{NH}_{4}{ }^{+}(\mathrm{aq})$ and $\mathrm{OH}^{-}(\mathrm{aq})$ ions. i.e. Therefore, $\mathrm{NH}_{3}(\mathrm{aq})$ is classified as a Brønsted base because it can accept a $\mathrm{H}^{+}$ion.

## Lewis acids and bases

G.N. Lewis in 1923 defined an acid as a species which accepts an electron pair and a base as a species which donates an electron pair. As far as bases are concerned, there is not much difference between Brönsted-Lowry and Lewis concepts, as the base provides
a lone pair in both the cases. However, in Lewis concept many acids do not have protons. A typical example is reaction of electron deficient species $\mathrm{BF}_{3}$ with $\mathrm{NH}_{3} . \mathrm{BF}_{3}$ does not have a proton but still acts as an acid and reacts with $\mathrm{NH}_{3}$ by accepting its lone pair of electrons. The reaction can be represented by,

$$
\mathrm{BF}_{3}+: \mathrm{NH}_{3} \rightarrow \mathrm{BF}_{3}: \mathrm{NH}_{3}
$$

Electron deficient species like $\mathrm{AlCl}_{3}, \mathrm{Co}^{3+}, \mathrm{Mg}^{2+}$, etc. can act as Lewis acids while species like $\mathrm{H}_{2} \mathrm{O}, \mathrm{NH}_{3}, \mathrm{OH}^{-}$etc. which can donate a pair of electrons, can act as Lewis bases.

### 2.2.2 Conjugate acid - base pairs

Brønsted definition of acids and bases can further be extended to the concept of the conjugate acid-base pair, which can be defined as an acid and its conjugate base or a base and its conjugate acid. The conjugate base of a Brønsted acid is the species that remains when one proton has been removed from the acid. Conversely, a conjugate acid results from the addition of a proton to a Brønsted base.
Consider the partial dissolution of $\mathrm{NH}_{3}(\mathrm{aq})$ in water.

A basic solution is formed due to the presence of hydroxyl ions. In this reaction, water molecule acts as proton donor and ammonia molecule acts as proton acceptor and are thus, called Lowry-Brönsted acid and base, respectively. In the reverse reaction, $\mathrm{H}^{+}$is transferred from $\mathrm{NH}_{4}{ }^{+}(\mathrm{aq})$ to $\mathrm{OH}^{-}(\mathrm{aq})$. In this case, $\mathrm{NH}_{4}{ }^{+}(\mathrm{aq})$ acts as a Bronsted acid while $\mathrm{OH}^{-}$acted as a Brönsted base. The acid-base pair that differs only by one proton is called a conjugate acid-base pair. Therefore, $\mathrm{OH}^{-}(\mathrm{aq})$ is called the conjugate base of an acid $\mathrm{H}_{2} \mathrm{O}$ and $\mathrm{NH}_{4}{ }^{+}(\mathrm{aq})$ is called conjugate acid of the base $\mathrm{NH}_{3}(\mathrm{aq})$. If Brönsted acid is a strong acid, its conjugate base is a weak base and vice versa. It may be noted that conjugate acid has one extra proton and each conjugate base has one less proton.

Consider the example of ionization of acetic acid $\mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})$ in water. $\mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})$ acts as an acid by donating a proton to $\mathrm{H}_{2} \mathrm{O}$ molecule which acts as a base.

It can be seen in the above equation, that water acts as a base because it accepts the proton. The species $\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})$ is produced when water accepts a proton from $\mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})$. Therefore, $\mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})$ is a conjugate base of $\mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})$ acid and $\mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})$ is the conjugate acid of base $\mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})$. Similarly, $\mathrm{H}_{2} \mathrm{O}$ is a conjugate base of the acid $\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})$ and $\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})$ is the conjugate acid of base $\mathrm{H}_{2} \mathrm{O}$.

It is interesting to observe the dual role of water as an acid and a base. In case of reaction with $\mathrm{CH}_{3} \mathrm{COOH}$ acid, water acts as a base while in case of ammonia it acts as an acid by donating a proton.

## Example 2.12

(i) What will be the conjugate bases for the following Brönsted acids: HF, $\mathrm{H}_{2} \mathrm{SO}_{4}$ and $\mathrm{HCO}_{3}^{-}$

## Answer

The conjugate bases should have one proton less in each case and therefore the corresponding conjugate bases are: $\mathrm{F}^{-}, \mathrm{HSO}_{4}{ }^{-}$and $\mathrm{CO}_{3}{ }^{2-}$ respectively.
(ii) Write the conjugate acids for the following Brönsted bases: $\mathrm{NH}_{2}{ }^{-}, \mathrm{NH}_{3}$ and $\mathrm{HCOO}^{-}$.

## Answer

The conjugate acid should have one extra proton in each case and therefore the corresponding conjugate acids are: $\mathrm{NH}_{3}, \mathrm{NH}_{4}{ }^{+}$and HCOOH respectively.

### 2.2.3 Ionization of acids and bases

Arrhenius concept of acids and bases becomes useful in case of ionization of acids and bases as mostly ionizations in chemical and biological systems occur in aqueous medium. Strong acids like perchloric acid $\left(\mathrm{HClO}_{4}\right)$, hydrochloric acid $(\mathrm{HCl})$, hydrobromic acid $(\mathrm{HBr})$, hyrdoiodic acid $(\mathrm{HI})$, nitric acid $\left(\mathrm{HNO}_{3}\right)$ and sulphuric acid $\left(\mathrm{H}_{2} \mathrm{SO}_{4}\right)$ are termed strong because they are almost completely dissociated into their constituent ions in an aqueous medium, thereby acting as proton $\left(\mathrm{H}^{+}\right)$donors. Similarly, strong bases like lithium hydroxide $(\mathrm{LiOH})$, sodium hydroxide $(\mathrm{NaOH})$, potassium hydroxide $(\mathrm{KOH})$, caesium hydroxide $(\mathrm{CsOH})$ and barium hydroxide $\mathrm{Ba}(\mathrm{OH})_{2}$ are almost completely dissociated into ions in an aqueous medium giving hydroxyl ions, $\mathrm{OH}-$. According to Arrhenius concept they are strong acids and bases as they are able to completely dissociate and produce $\mathrm{H}_{3} \mathrm{O}^{+}$and $\mathrm{OH}^{-}$ions respectively in the medium.

Alternatively, the strength of an acid or base may also be gauged in terms of BrönstedLowry concept of acids and bases, wherein a strong acid means a good proton donor and
a strong base implies a good proton acceptor. Consider, the acid-base dissociation equilibrium of a weak acid HA ,

As we saw earlier, acid (or base) dissociation equilibrium is dynamic involving a transfer of proton in forward and reverse directions. Now, the question arises that if the equilibrium is dynamic then with passage of time which direction is favoured? What is the driving force behind it? In order to answer these questions we shall deal into the issue of comparing the strengths of the two acids (or bases) involved in the dissociation equilibrium. Consider the two acids HA and $\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})$ present in the above mentioned acid-dissociation equilibrium. We have to see which amongst them is the stronger proton donor. Whichever exceeds in its tendency of donating a proton over the other shall be termed the stronger acid and the equilibrium will shift in the direction of the weaker acid. Say, if $\mathrm{HA}\left({ }_{(\mathrm{aq})}\right.$ is a stronger acid than $\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})$, and then $\mathrm{HA}(\mathrm{aq})$ will donate protons and not $\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})$, and the solution will mainly contain $\mathrm{A}^{-}(\mathrm{aq})$ and $\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})$ ions. The equilibrium moves in the direction of formation of weaker acid and weaker base because the stronger acid donates a proton to the stronger base.

It follows that as a strong acid dissociates completely in water, the resulting base formed would be very weak i.e., strong acids have very weak conjugate bases. Strong acids like perchloric acid $\left(\mathrm{HClO}_{4}\right)$, hydrochloric acid $(\mathrm{HCl})$, hydrobromic acid $(\mathrm{HBr})$, hydroiodic acid $(\mathrm{HI})$, nitric acid $\left(\mathrm{HNO}_{3}\right)$ and sulphuric acid $\left(\mathrm{H}_{2} \mathrm{SO}_{4}\right)$ will give conjugate base ions $\mathrm{ClO}_{4}^{-}, \mathrm{Cl}^{-}, \mathrm{Br}^{-}, \mathrm{I}^{-}, \mathrm{NO}_{3}{ }^{-}$and $\mathrm{HSO}_{4}^{-}$, which are much weaker bases than $\mathrm{H}_{2} \mathrm{O}$. Similarly a very strong base would give a very weak conjugate acid. On the other hand, a weak acid say HA is only partially dissociated in aqueous medium and thus, the solution mainly contains undissociated HA molecules. Typical weak acids are nitrous acid $\left(\mathrm{HNO}_{2}\right)$, hydrofluoric acid (HF) and acetic acid $\left(\mathrm{CH}_{3} \mathrm{COOH}\right)$. It should be noted that the weak acids have very strong conjugate bases. For example, $\mathrm{NH}_{2}{ }^{-}, \mathrm{O}^{2-}$ and $\mathrm{H}^{-}$are very good proton acceptors and thus, much stronger bases than $\mathrm{H}_{2} \mathrm{O}$.

Therefore we can summarize the following on conjugate acid-base pairs.

- If an acid is strong, its conjugate base has no measurable strength. Thus the $\mathrm{Cl}^{-}$ ion, which is the conjugate base of the strong acid HCl , is an extremely weak base.
- $\mathrm{H}_{3} \mathrm{O}^{+}$is the strongest acid that can exist in aqueous solution. Acids stronger than $\mathrm{H}_{3} \mathrm{O}^{+}$react with water to produce $\mathrm{H}_{3} \mathrm{O}^{+}$and their conjugate bases. Thus HCl , which is a stronger acid than $\mathrm{H}_{3} \mathrm{O}^{+}$, reacts with water completely to form $\mathrm{H}_{3} \mathrm{O}^{+}$ and $\mathrm{Cl}^{-}$:

$$
\mathrm{HCl}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightarrow \mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})+\mathrm{Cl}^{-}(\mathrm{aq})
$$

Acids weaker than $\mathrm{H}_{3} \mathrm{O}^{+}$react with water to a much smaller extent, producing $\mathrm{H}_{3} \mathrm{O}^{+}$and their conjugate bases. For example, the following equilibrium lies primarily to the left:

$$
\mathrm{HF}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq})
$$

- The $\mathrm{OH}^{-}$ion is the strongest base that can exist in aqueous solution. Bases stronger than $\mathrm{OH}^{-}$react with water to produce $\mathrm{OH}^{-}$and their conjugate acids. For example, the oxide ion $\left(\mathrm{O}^{2-}\right)$ is a stronger base than $\mathrm{OH}^{-}$, so it reacts with water completely as follows:

$$
\mathrm{O}^{2-}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightarrow 2 \mathrm{OH}^{-}(\mathrm{aq})
$$

For this reason the oxide ion does not exist in aqueous solutions.

### 2.2.4 The ionization constant of water and its ionic product

Water and some substances are unique in their ability of acting both as an acid and a base. We have seen this in case of water in the section above. In the presence of an acid HA, it accepts a proton and acts as the base while in the presence of a base, $\mathrm{B}^{-}$it acts as an acid by donating a proton. In pure water, one $\mathrm{H}_{2} \mathrm{O}$ molecule donates a proton and acts as an acid and another water molecule accepts a proton and acts as a base at the same time. The following equilibrium exists:

$$
\begin{gathered}
\mathrm{H}_{2} \mathrm{O}(\mathrm{l})+\underset{2}{\mathrm{H}_{2} \mathrm{O}(\mathrm{l})} \rightleftharpoons \underset{\text { acid }}{\text { base }} \underset{\text { conjugate conjugate }}{\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})+}+\mathrm{OH}^{-}(\mathrm{aq}) \\
\text { base }
\end{gathered}
$$

The dissociation constant for the reaction is represented by,

$$
K=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]\left[\mathrm{OH}^{-}(\mathrm{aq})\right]}{\left[\mathrm{H}_{2} \mathrm{O}(\mathrm{l})\right]^{2}}
$$

The concentration of water is omitted from the denominator as water is a pure liquid and its concentration remains constant (Concentration of water in $1.00 \mathrm{dm}^{3}$ of solution is $10^{3} \mathrm{~g} \mathrm{dm}^{-3} / 18 \mathrm{~g} \mathrm{~mol}^{-1}=55.55 \mathrm{~mol} \mathrm{dm}^{-3}$ is a constant) . Therefore, incorporation of $\left[\mathrm{H}_{2} \mathrm{O}(1)\right]$ into the equilibrium constant to give a new constant, $K_{\mathrm{w}}$, which is called the ionic product of water.
i.e, $K\left[\mathrm{H}_{2} \mathrm{O}(\mathrm{l})\right]^{2}=K_{\mathrm{w}}=\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]\left[\mathrm{OH}^{-}(\mathrm{aq})\right]$

The concentrations of $\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})$ and $\mathrm{OH}^{-}(\mathrm{aq})$ have been found out experimentally as $1.0 \times 10^{-7} \mathrm{~mol} \mathrm{dm}^{-3}$ at 298 K . As dissociation of water produces equal number of $\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})$ and $\mathrm{OH}^{-}(\mathrm{aq})$ ions, the value of $K_{\mathrm{w}}$ at 298 K is,

$$
K_{\mathrm{w}}=\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]\left[\left[\mathrm{OH}^{-}(\mathrm{aq})\right]\right]=\left(1 \times 10^{-7} \mathrm{~mol} \mathrm{dm}^{-3}\right)^{2}=1 \times 10^{-14} \mathrm{~mol}^{2} \mathrm{dm}^{-6}
$$

It has to be noted that the $K_{w}$ is temperature dependent and is an equilibrium constant. When $\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]=\left[\mathrm{OH}^{-}(\mathrm{aq})\right]$, the aqueous solution is said to be neutral. In an acidic solution there is an excess of hydronium ions and $\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]>\left[\mathrm{OH}^{-}(\mathrm{aq})\right]$. In a basic solution there is an excess of hydroxide ions, so $\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]<\left[\mathrm{OH}^{-}(\mathrm{aq})\right]$.

### 2.2.5 The $\mathbf{p H}$ scale

Hydronium ion concentration in molarity is more conveniently expressed on a logarithmic scale known as the $\mathbf{p H}$ scale. The pH of a solution is defined as the negative logarithm to base 10 of the activity $\left(a_{\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})}\right)$ or $\left(a_{\mathrm{H}^{+}(\mathrm{aq})}\right)$ of the hydronium or hydrogen ion. In dilute solutions $\left(<0.01 \mathrm{~mol} \mathrm{dm}^{-3}\right)$, activity of hydrogen ion is equal in magnitude to molarity represented by $\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]$. It should be noted that activity has no units and is defined as:

$$
\left(a_{\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})}\right) \text { or }\left(a_{\mathrm{H}^{+}(\mathrm{aq})}\right)=\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right] / 1 \mathrm{~mol} \mathrm{dm}^{-3}
$$

Therefore, from the definition of pH is

$$
\mathrm{pH}=-\log \left(a_{\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})}\right)=-\log \left\{\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right] / 1 \mathrm{~mol} \mathrm{dm}^{-3}\right\}
$$

As the $\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]$ has units mol dm ${ }^{-3}$,
$\mathrm{pH}=-\log \left\{\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right] \mathrm{mol} \mathrm{dm}^{-3} / \mathrm{mol} \mathrm{dm}^{-3}\right\}$
$\mathrm{pH}=-\log \left\{\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]\right\}$
That is, pH value has no units.
Thus, an acidic solution of $\mathrm{HCl}\left(10^{-2} \mathrm{~mol} \mathrm{dm}^{-3}\right)$ will have a $\mathrm{pH}=2$. Similarly, a basic solution of NaOH having $\left[\mathrm{OH}^{-}\right]=10^{-4} \mathrm{~mol} \mathrm{dm}^{-3}$ and $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=10^{-10} \mathrm{~mol} \mathrm{dm}^{-3}$ will have a $\mathrm{pH}=10$. At $25^{\circ} \mathrm{C}$, pure water has a concentration of hydronium or hydrogen ions, $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$ or $\left[\mathrm{H}^{+}\right]=10^{-7} \mathrm{~mol} \mathrm{dm}^{-3}$. Hence, the pH of pure water is given as:

$$
\mathrm{pH}=-\log \left(10^{-7} \mathrm{~mol} \mathrm{dm}^{-3} / \mathrm{mol} \mathrm{dm}^{-3}\right)=7
$$

Acidic solutions possess a concentration of hydrogen ions, $\left[\mathrm{H}^{+}\right]>10^{-7} \mathrm{~mol} \mathrm{dm}^{-3}$, while basic solutions possess a concentration of hydrogen ions, $\left[\mathrm{H}^{+}\right]<10^{-7} \mathrm{~mol} \mathrm{dm}^{-3}$. Thus, we can summarisethat
Acidic solution has $\mathrm{pH}<7$
Basic solution has $\mathrm{pH}>7$
Neutral solution has $\mathrm{pH}=7$

Figure 2.15 Simple visualization of the pH scale. At pH 7.0 solutions are said to be neutral. Proceeding to the lower pH values increases the acidity while the otherway increases the basisity of solutions.

## G.C.E. (A/L) CHEMISTRY: UNIT 12 Chemical Equilibrium

$$
K_{\mathrm{w}}=\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]\left[\mathrm{OH}^{-}(\mathrm{aq})\right]
$$

Taking negative logarithm on both sides of equation, we obtain

$$
\begin{gathered}
-\log K_{\mathrm{w}}=-\log \left\{\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]\left[\mathrm{OH}^{-}(\mathrm{aq})\right]\right\} \\
\mathrm{p} K_{\mathrm{w}}=- \\
-\log \left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]-\log \left[\mathrm{OH}^{-}(\mathrm{aq})\right] \\
\mathrm{p} K_{\mathrm{w}} \quad=\mathrm{pH}+\mathrm{pOH} \\
\quad \text { or } \\
\mathrm{pH}+\mathrm{pOH}=14
\end{gathered}
$$

Note that although $K_{\mathrm{w}}$ may change with temperature, the variations in pH with temperature are so small that we often ignore it. $\mathrm{p} K_{\mathrm{w}}$ is a very important quantity for aqueous solutions and controls the relative concentrations of hydrogen and hydroxyl ions as their product is a constant. It should be noted that as the pH scale is logarithmic, a change in pH by just one unit also means change in $\left[\mathrm{H}^{+}\right]$by a factor of 10 . Similarly, when the hydrogen ion concentration, $\left[\mathrm{H}^{+}\right]$changes by a factor of 100 , the value of pH changes by 2 units. Now you can realize why the change in pH with temperature is often ignored.

Measurement of pH of a solution is very essential as its value should be known when dealing with biological and cosmetic applications. The pH of a solution can be found roughly with the help of pH paper that gives different colours in solutions of different pH . The $p \mathrm{H}$ in the range of 1-14 can be determined with an accuracy of $\sim 0.5$ using a pH paper. In the laboratory, the pH of a solution is also measured with a pH meter.

Let's consider following examples involving calculations based on pH .

## Example 2.13

Calculate pH of a $1.0 \times 10^{-4} \mathrm{~mol} \mathrm{dm}^{-3}$ solution of HCl .

## Answer

$p \mathrm{H}=-\log \left(10^{-4} \mathrm{~mol} \mathrm{dm}^{-3} / \mathrm{mol} \mathrm{dm}^{-3}\right)=4$

## Example 2.14

In a NaOH solution $\left[\mathrm{OH}^{-}\right]$is $1.0 \times 10^{-4} \mathrm{~mol} \mathrm{dm}^{-3}$. Calculate the pH of the solution.

## Answer

$\left[\mathrm{OH}^{-}\right]=1.0 \times 10^{-4} \mathrm{~mol} \mathrm{dm}^{-3}$
$\mathrm{pOH}=-\log \left(10^{-4} \mathrm{~mol} \mathrm{dm}^{-3} / \mathrm{mol} \mathrm{dm}^{-3}\right)=4$ Therefore, $\mathrm{pH}=14-4=10$
or
$\left[\mathrm{OH}^{-}\right]=1.0 \times 10^{-4} \mathrm{~mol} \mathrm{dm}^{-3}$ gives $\left[\mathrm{H}^{+}\right]=1.0 \times 10^{-10} \mathrm{~mol} \mathrm{dm}^{-3}$
$\mathrm{pH}=-\log \left(10^{-10} \mathrm{~mol} \mathrm{dm}^{-3} / \mathrm{mol} \mathrm{dm}^{-3}\right)=10$

## G.C.E. (A/L) CHEMISTRY : UNIT 12

## Example 2.15

Calculate pH of a $1.0 \times 10^{-8} \mathrm{~mol} \mathrm{dm}^{-3}$ solution of HCl .

## Answer

In this calculation some may make a wrong approach by taking pH as
$\mathrm{pH}=-\log \left(10^{-8} \mathrm{~mol} \mathrm{dm}^{-3} / \mathrm{mol} \mathrm{dm}^{-3}\right)=8$
One should note that here the $\left[\mathrm{H}^{+}\right]$from HCl is less than that coming from the selfionization of water (i.e. $1.0 \times 10^{-7} \mathrm{~mol} \mathrm{dm}^{-3}$ ). Therefore, we should consider the $\left[\mathrm{H}^{+}\right]$ generated from both HCl and water. That is, $\left[\mathrm{H}^{+}\right]$from the given HCl solution is $1.0 \times 10^{-8} \mathrm{~mol} \mathrm{dm}^{-3}$ and take that from water as $x$.
Therefore, $\left[\mathrm{OH}^{-}\right]=x$ and $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=10^{-8}+x$
$K_{\mathrm{w}}=\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]\left[\mathrm{OH}^{-}(\mathrm{aq})\right]=10^{-14}=\left(10^{-8}+x\right) x$
$x^{2}+10^{-8} x-10^{-14}=0$
Solving the above quadratic equation, we get
$\left[\mathrm{OH}^{-}\right]=9.5 \times 10^{-8} \mathrm{~mol} \mathrm{dm}^{-3}$ and hence $\mathrm{pOH}=7.02$
Therefore, $\mathrm{pH}=6.98$

In the above calculations in examples, it was easy to decide the concentration of $\left[\mathrm{H}^{+}\right]$and [ $\mathrm{OH}^{-}$] as we know that HCl and NaOH are a strong acid and a base, respectively, giving rise to complete ionization. However, when we have aqueous solutions of weak acids or bases, it needs some more information on the system as they undergo partial dissociation. In the next section we consider dissociation of weak acids and bases with the emphasis on their equlibria.

### 2.2.6 Weak acids and their ionization (dissociation) constant

Consider a weak monoprotic acid, HA. Its ionization in water is represented by

$$
\mathrm{HA}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})+\mathrm{A}^{-}(\mathrm{aq})
$$

The equilibrium expression for this ionization is

$$
K=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]\left[\mathrm{A}^{-}(\mathrm{aq})\right]}{[\mathrm{HA}(\mathrm{aq})]\left[\mathrm{H}_{2} \mathrm{O}(\mathrm{l})\right]}
$$

We can write,

$$
K\left[\mathrm{H}_{2} \mathrm{O}(\mathrm{l})\right]=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]\left[\mathrm{A}^{-}(\mathrm{aq})\right]}{[\mathrm{HA}(\mathrm{aq})]}
$$

Taking $K\left[\mathrm{H}_{2} \mathrm{O}(\mathrm{l})\right]=K_{\mathrm{a}}$, as a constant, because $\left[\mathrm{H}_{2} \mathrm{O}(\mathrm{l})\right]$ is a constant, we can write

## G.C.E. (A/L) CHEMISTRY: UNIT 12 Chemical Equilibrium

$$
K_{\mathrm{a}}=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]\left[\mathrm{A}^{-}(\mathrm{aq})\right]}{[\mathrm{HA}(\mathrm{aq})]}
$$

$K_{\mathrm{a}}$ is called the dissociation or ionization constant of the weak acid which is the equilibrium constant for the ionization of the acid. At a given temperature, the strength of the acid HA is measured quantitatively by the magnitude of $K_{\mathrm{a}}$. Large $K_{\mathrm{a}}$, indicates that the acid is stronger, which means a greater the concentration of $\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]$ or $\left[\mathrm{H}^{+}(\mathrm{aq})\right]$ ions at equilibrium due to its ionization in aqueous solution. Only weak acids have $K_{\mathrm{a}}$ values associated with them.

The above definition of the acid ionization constant can also be treated as follows considering the partial ionization of HA in aqueous solution. Assuming that the initial concentration of the undissociated acid is $\boldsymbol{c}$ and its extent of ionization (or degree of ionization) is $\boldsymbol{\alpha}$, we can express the equilibrium as,

| $\mathrm{HA}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})$ | $\rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})+\mathrm{A}^{-}(\mathrm{aq})$ |  |
| :--- | :---: | :---: |
| $c$ | 0 | 0 |
| $-c \alpha$ | $+c \alpha$ | $+c \alpha$ |
| $c(1-\alpha)$ | $c \alpha$ | $c \alpha$ |

$$
\begin{gathered}
\therefore K_{\mathrm{a}}=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]\left[\mathrm{A}^{-}(\mathrm{aq})\right]}{[\mathrm{HA}(\mathrm{aq})]}=\frac{\boldsymbol{c} \boldsymbol{\alpha} \cdot \boldsymbol{c} \boldsymbol{\alpha}}{\boldsymbol{c}(\mathbf{1}-\boldsymbol{\alpha})}=\frac{\boldsymbol{c} \boldsymbol{\alpha}^{2}}{(1-\alpha)} \\
\therefore K_{\mathrm{a}}=\frac{\boldsymbol{c} \alpha^{2}}{(1-\alpha)}
\end{gathered}
$$

As the ionization of a weak acid is very small, we can assume that $\alpha$ is very small or $(1-\alpha) \sim 1$. Hence, $\therefore K_{\mathrm{a}}=c \alpha^{2}$
This is called Ostwald's law of dilution.
Note: This is valid for weak bases in aqueous solutions too.
The values of the ionization constants of some weak acids at 298 K are given in the following table.

Table 2.2 The ionization constants of some selected weak acids (at 298K)

| Acid | $\boldsymbol{K}_{\mathrm{a}}$ |
| :--- | :--- |
| Hydrofluoric Acid (HF) | $3.5 \times 10^{-4}$ |
| Nitrous Acid $\left(\mathrm{HNO}_{2}\right)$ | $4.5 \times 10^{-4}$ |
| Acetic Acid $\left(\mathrm{CH}_{3} \mathrm{COOH}\right)$ | $1.74 \times 10^{-5}$ |
| Benzoic Acid $\left(\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{COOH}\right)$ | $6.50 \times 10^{-5}$ |
| Hypochlorous Acid (HCIO) | $3.00 \times 10^{-8}$ |
| Hydrocyanic Acid $(\mathrm{HCN})$ | $4.90 \times 10^{-10}$ |
| Phenol $\left(\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{OH}\right)$ | $1.30 \times 10^{-10}$ |

Note: $K_{\mathrm{a}}$ is a dimensionless quantity with the understanding that the standard state concentration of all species is $1 \mathrm{~mol} \mathrm{dm}{ }^{-3}$. That is all the concentration terms appearing in the equilibrium constant expression is divided by $1 \mathrm{~mol} \mathrm{dm}{ }^{-3}$. Otherwise we indicate the units as relevant to the equilibrium constant expression.

The pH scale for the hydrogen ion concentration has been so useful that besides $\mathrm{p} K_{\mathrm{w}}$ $\left(-\log K_{\mathrm{w}}\right)$, it has been extended to other species and quantities. Thus, we have:

$$
\mathrm{p} K_{\mathrm{a}}=-\log \left(K_{\mathrm{a}}\right)
$$

Knowing the ionization constant, $K_{\mathrm{a}}$ of an acid and its initial concentration $\boldsymbol{c}$, it is possible to calculate the equilibrium concentration of all species and also the degree of ionization of the acid and the pH of the solution.

A general step-wise approach can be adopted to evaluate the pH of a weak electrolyte as follows:

Step 1. The species present before dissociation are identified as Brönsted-Lowry acids/ bases.
Step 2. Balanced equations for all possible reactions i.e., with a species acting both as acids as well as bases are written.
Step 3. The reaction with the higher $K_{\mathrm{a}}$ is identified as the primary reaction whilst the other is a subsidiary reaction.
Step 4. Enlist in a tabular form the following values for each of the species in the primary reaction.
(a) Initial concentration, $\boldsymbol{c}$
(b) Change in concentration on proceeding to equilibrium in terms of $\boldsymbol{\alpha}$, degree of ionization
(c) Equilibrium concentration

Step 5. Substitute equilibrium concentrations into equilibrium constant equation for the principal reaction and solve for $\alpha$.
Step 6. Calculate the concentration of species in the principal reaction.
Step 7. Calculate $\mathrm{pH}=-\log \left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$or calculate $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$once pH is known using $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=10^{-\mathrm{pH}}$

## G.C.E. (A/L) CHEMISTRY : UNIT 12

Chemical Equilibrium
The following example(s) illustrate(s) the above mentioned approach in calculating pH .

## Example 2.16

The ionization constant of HF is $3.2 \times 10^{-4}$ at 298 K . Calculate the degree of dissociation of HF in its $0.20 \mathrm{~mol} \mathrm{dm}^{-3}$ solution. Calculate the concentration of all species present $\left(\mathrm{H}_{3} \mathrm{O}^{+}, \mathrm{F}^{-}\right.$and HF$)$ in the solution and its pH .

## Answer

## Procedure I:

The following proton transfer reactions are possible:

$$
\begin{align*}
& \mathrm{HF}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq})----  \tag{1}\\
& \mathrm{H}_{2} \mathrm{O}(\mathrm{l})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})+\mathrm{OH}^{-}(\mathrm{aq}) \tag{2}
\end{align*}
$$

As $K_{\mathrm{a}}\left(3.2 \times 10^{-4}\right) \gg K_{\mathrm{w}}\left(1.0 \times 10^{-14}\right)$, we can understand that reaction (1) is the major reaction.

|  | $\mathrm{HF}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})$ | $+\mathrm{F}(\mathrm{aq})$ |  |
| :--- | :--- | :---: | :---: | :--- |
| Initial concentration $/ \mathrm{mol} \mathrm{dm}$ |  |  |  |
| -3 | 0.2 | 0 | 0 |
| Concentration hacnge $/ \mathrm{mol} \mathrm{dm}^{-3}$ | $-0.2 \alpha$ | $+0.2 \alpha$ | $+0.2 \alpha$ |
| $\therefore$ Equilibrium concentration $/$ | $0.2(1-\alpha)$ | $+0.2 \alpha$ | $+0.2 \alpha$ |
| $\mathrm{~mol} \mathrm{dm}^{-3}$ |  |  |  |

Substituting equilibrium concentrations in the equilibrium reaction for the principal reaction gives:

$$
\therefore K_{\mathrm{a}}=\frac{0.2 \alpha \times 0.2 \alpha}{0.2(1-\alpha)}=\frac{(0.2 \alpha)^{2}}{0.2(1-\alpha)}
$$

As the acid considered is weak, we can assume that the ionization is small compared to the initial concentration of the acid $\therefore(\mathbf{1}-\alpha) \sim \mathbf{1}$ or $\mathbf{0 . 2}(\mathbf{1}-\alpha) \sim \mathbf{0 . 2}$
Substituting in $K_{\mathrm{a}}=\frac{0.2 \alpha \times 0.2 \alpha}{0.2(1-\alpha)} \sim \frac{(0.2 \alpha)^{2}}{0.2}=3.2 \times 10^{-4}$

$$
\begin{gathered}
\alpha^{2}=1.6 \times 10^{-3} \\
\alpha=4.0 \times 10^{-2}
\end{gathered}
$$

$\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=\left[\mathrm{F}^{-}\right]=c \alpha=0.2 \mathrm{~mol} \mathrm{dm}^{-3} \times 0.04=8.0 \times 10^{-3} \mathrm{~mol} \mathrm{dm}^{-3}$
$[\mathrm{HF}]=c(1-\alpha)=0.2 \mathrm{~mol} \mathrm{dm}^{-3}(1-0.04)=19.2 \times 10^{-2} \mathrm{~mol} \mathrm{dm}^{-3}$

Hence, $\mathrm{pH}=-\log \left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=-\log \left(8.0 \times 10^{-3}\right)=2.10$
Validity of the approximation we made can be checked by calculating the percent value of the ionization with respect to the initial concentration of the acid. When the percent value is less than $5 \%$ we usually accepts the approximation and otherwise it is necessary to solve the quadratic equation to obtain the value of $\alpha$.

From the above estimated value 0.04 we get,

$$
\frac{0.04}{0.20} \times 100 \%=2.0 \%
$$

Thus the approximation used can be accepted.
We can further confirm/clarify the above approximation by obtaining the value of $\boldsymbol{\alpha}$ after solving the quadratic equation and taking the relative percent deviation of it.

For the above example: $K_{\mathrm{a}}=\frac{0.2 \alpha \times \mathbf{0 . 2 \alpha}}{\mathbf{0 . 2 ( 1 - \alpha )}}=3.2 \times 10^{-4}$
We obtain the following quadratic equation:
$\alpha^{2}+1.6 \times 10^{-3} \alpha-1.6 \times 10^{-3}=0$
Note: The values for $x$ of the quadratic equation, $a x^{2}+b x+c=0$ are given by

$$
x=\frac{-\mathrm{b} \pm \sqrt{\left(\mathrm{b}^{2}-4 \mathrm{ac}\right)}}{2 \mathrm{a}}
$$

The quadratic equation with $\alpha$ can be solved and the two values of $\alpha$ are:
$\alpha=+3.92 \times 10^{-2}$ and $-4.08 \times 10^{-2}$
The negative value is not acceptable and hence

$$
\alpha=3.92 \times 10^{-2}
$$

Now we can calculate the relative percent deviation as

$$
\frac{0.04-3.92 \times 10^{-2}}{0.04} \times 100 \%=2.0 \%
$$

We can see that the close similarity in the above two methods and therefore usually we make the said approximation for this type of calculations.

Note: The above approximation can be applied in the cases when the initial concentration of the acid/base is much larger (at least 3 orders of magnitude) than the acid ionization constant $K_{\mathrm{a}}$ of the acid.

In the above example: initial concentration is $0.2 \mathrm{~mol} \mathrm{dm}^{-3}$ and $K_{\mathrm{a}}=3.2 \times 10^{-4}$, so the ratio is

$$
\frac{2.0 \times 10^{-1}}{3.2 \times 10^{-4}} \sim^{10^{3}}
$$

Therefore, we can make the approximation.

## Procedure II:

The example above can also be treated as follows. We know that the major reaction in system is,

$$
\mathrm{HF}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})+\mathrm{F}^{-}(\mathrm{aq})
$$

Now taking the dissociated concentration or change in concentration as $x$, we can write,

|  | $\mathrm{HF}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})$ | $\rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})$ | + | $\mathrm{F}^{-}(\mathrm{aq})$ |
| :--- | :--- | :--- | :--- | :---: |
| Initial concentration $/ \mathrm{mol} \mathrm{dm}^{-3}$ | 0.2 | 0 | 0 |  |
| Concentration change $\left(\mathrm{mol} \mathrm{dm}^{-3}\right)$ | $-x$ | $+x$ | $+x$ |  |
| $\therefore$ Equilibrium concentration/ | $0.2-x$ | $+x$ | $+x$ |  |
| mol dm |  |  |  |  |

Substituting equilibrium concentrations in the equilibrium reaction gives:

$$
\therefore K_{\mathrm{a}}=\frac{x \times x}{(0.2-x)}=\frac{(x)^{2}}{(0.2-x)}
$$

As the acid considered is weak, we can assume that the ionization is small compared to the initial concentration of the acid $\mathbf{0 . 2 - \boldsymbol { x } \sim \mathbf { 0 . 2 }}$
Substituting in $K_{\mathrm{a}} \sim \frac{(x)^{2}}{0.2}=3.2 \times 10^{-4}$

$$
\begin{gathered}
x^{2}=6.4 \times 10^{-5} \\
x=8.0 \times 10^{-3} \mathrm{~mol} \mathrm{dm}^{-3}
\end{gathered}
$$

And we have
$\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=\left[\mathrm{F}^{-}\right]=x=8.0 \times 10^{-3} \mathrm{~mol} \mathrm{dm}^{-3}$
$[\mathrm{HF}]=0.20-x=0.2-0.008=19.2 \times 10^{-2} \mathrm{~mol} \mathrm{dm}^{-3}$
Hence, $\mathrm{pH}=-\log \left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=-\log \left(8.0 \times 10^{-3}\right)=2.10$

Note that the procedure II gives us the values of equilibrium concentrations directly.

## Example 2.17

The pH of $0.10 \mathrm{~mol} \mathrm{dm}^{-3}$ monobasic acid $\mathrm{HA}(\mathrm{aq})$ is 4.50 . Calculate the concentration of species $\mathrm{H}^{+}(\mathrm{aq}), \mathrm{A}^{-}(\mathrm{aq})$ and $\mathrm{HA}(\mathrm{aq})$ at equilibrium. Also, determine the value of $\boldsymbol{K}_{\mathrm{a}}$ and $\mathbf{p} K_{a}$ of the monobasic acid.

## G.C.E. (A/L) CHEMISTRY : UNIT 12

```
Answer
pH=- log[H3O
Therefore, }[\mp@subsup{\textrm{H}}{3}{}\mp@subsup{\textrm{O}}{}{+}]=1\mp@subsup{0}{}{-\textrm{pH}}=1\mp@subsup{0}{}{-4.50}=3.16\times1\mp@subsup{0}{}{-5
[H3}\mp@subsup{\textrm{O}}{}{+}]=[\mp@subsup{\textrm{A}}{}{-}]=3.16\times1\mp@subsup{0}{}{-5}\mp@subsup{\textrm{mol dm}}{}{-3
[HA}\mp@subsup{]}{\mathrm{ eqlbm }}{}=0.1-(3.16\times1\mp@subsup{0}{}{-5})~0.1 mol dm-3
```

We can summarize these as follows

| $\mathrm{HA}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons$ | $\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})+$ | $\mathrm{A}^{-}(\mathrm{aq})$ |
| :--- | :--- | :--- |
| 0.1 | 0 | 0 |
| $-3.16 \times 10^{-5}$ | $3.16 \times 10^{-5}$ | $3.16 \times 10^{-5}$ |
| $\left(0.10-3.16 \times 10^{-5}\right)$ | $3.16 \times 10^{-5}$ | $3.16 \times 10^{-5}$ |
| 0.10 | $3.16 \times 10^{-5}$ | $3.16 \times 10^{-5}$ |

Thus, $\boldsymbol{K}_{\mathrm{a}}=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]\left[\mathrm{A}^{-}(\mathrm{aq})\right]}{[\mathrm{HA}(\mathrm{aq})]}$
$\therefore K_{\mathrm{a}}=\left(3.16 \times 10^{-5}\right)^{2} / 0.1=1.0 \times 10^{-8} \mathrm{~mol} \mathrm{dm}^{-3}$
$\mathrm{p} K_{\mathrm{a}}=-\log \left(10^{-8}\right)=8$

### 2.2.7 Weak bases and base ionization constant

The ionization of base MOH can be represented by equation:

$$
\mathrm{BOH}(\mathrm{aq}) \rightleftharpoons \mathrm{B}^{+}(\mathrm{aq})+\mathrm{OH}^{-}(\mathrm{aq})
$$

We can write this reaction as,

$$
\mathrm{B}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{BH}^{+}(\mathrm{aq})+\mathrm{OH}^{-}(\mathrm{aq})
$$

In a weak base there is partial ionization of $\mathrm{MOH}\left(\right.$ (aq ) into $\mathrm{M}^{+}{ }_{(\mathrm{aq})}$ and $\mathrm{OH}^{-}($(aq) $)$, is similar to that of acid-dissociation equilibrium. The equilibrium constant for base ionization is called base ionization constant and is represented by $\boldsymbol{K}_{b}$. It can be expressed in terms of concentration in molarity of various species in equilibrium by the following equation:

$$
K=\frac{\left[\mathrm{BH}^{+}(\mathrm{aq})\right]\left[\mathrm{OH}^{-}(\mathrm{aq})\right]}{[\mathrm{B}(\mathrm{aq})]\left[\mathrm{H}_{2} \mathrm{O}(\mathrm{l})\right]}
$$

Similar to treatment in weak acids,

$$
\begin{gathered}
K\left[\mathrm{H}_{2} \mathrm{O}(\mathrm{l})\right]=\frac{\left[\mathrm{BH}^{+}(\mathrm{aq})\right]\left[\mathrm{OH}^{-}(\mathrm{aq})\right]}{[\mathrm{B}(\mathrm{aq})]} \\
K_{\mathrm{b}}=\frac{\left[\mathrm{BH}^{+}(\mathrm{aq})\right]\left[\mathrm{OH}^{-}(\mathrm{aq})\right]}{[\mathrm{B}(\mathrm{aq})]}
\end{gathered}
$$

or for the reaction, $\mathrm{BOH}(\mathrm{aq}) \rightleftharpoons \mathrm{B}^{+}(\mathrm{aq})+\mathrm{OH}^{-}(\mathrm{aq})$

$$
K_{\mathrm{b}}=\frac{\left[\mathrm{B}^{+}(\mathrm{aq})\right]\left[\mathrm{OH}^{-}(\mathrm{aq})\right]}{[\mathrm{BOH}(\mathrm{aq})]}
$$

Alternatively, if $c=$ initial concentration of base and $\alpha=$ degree of ionization of base, when equilibrium is reached, the equilibrium constant can be written as:

$$
\therefore K_{\mathrm{b}}=\frac{\boldsymbol{c} \alpha^{2}}{(1-\alpha)}
$$

The production of hydroxide ions in this base ionization reaction means that $\left[\mathrm{OH}^{-}(\mathrm{aq})\right]>\left[\mathrm{H}^{+}(\mathrm{aq})\right]$ and therefore $\mathrm{pH}>7$.

The values of the ionization constants of some weak bases at 298 K are given in the following table.

Table 2.3 The ionization constants of some selected weak bases (at 298K)

| Base | $\boldsymbol{K}_{\mathbf{b}}$ |
| :--- | :--- |
| Dimethylamine, $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{NH}$ | $5.40 \times 10^{-4}$ |
| Triethylamine, $\left(\mathrm{C}_{2} \mathrm{H}_{5}\right)_{3} \mathrm{~N}$ | $6.45 \times 10^{-5}$ |
| Ammonia, $\mathrm{NH}_{3}$ or $\mathrm{NH}_{4} \mathrm{OH}$ | $1.77 \times 10^{-5}$ |
| Pyridine, $\left.\mathrm{C}_{5} \mathrm{H}_{5} \mathrm{~N}\right)$ | $1.77 \times 10^{-9}$ |
| Aniline, $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NH}_{2}$ | $4.27 \times 10^{-10}$ |
| Urea, $\mathrm{CO}\left(\mathrm{NH}_{2}\right)_{2}$ | $1.30 \times 10^{-14}$ |

In solving problems involving weak bases, we follow the same procedure we used for weak acids. The main difference is that we calculate $\left[\mathrm{OH}^{-}(\mathrm{aq})\right]$ first rather than $\left[\mathrm{H}^{+}(\mathrm{aq})\right]$ and the following example shows this approach.

## Example 2.18

Calculate the pH of a $0.40 \mathrm{~mol} \mathrm{dm}^{-3}$ ammonia solution. $K_{\mathrm{b}}=1.80 \times 10^{-5}$

## Answer

The following equilibrium reaction exists and let $x$ be the equilibrium concentration of $\mathrm{NH}_{4}{ }^{+}(\mathrm{aq})$ and $\mathrm{OH}^{-}(\mathrm{aq})$ ions in mold $\mathrm{m}^{-3}$, we summarize:

|  | $\mathrm{NH}_{3}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})$ | $\rightleftharpoons \mathrm{NH}_{4}{ }^{+}(\mathrm{aq})+\mathrm{OH}^{-}(\mathrm{aq})$ |  |
| :--- | :--- | :---: | :---: |
| Initial concentration $/ \mathrm{mol} \mathrm{dm}$ |  |  |  |
| Concentration change $/ \mathrm{mol} \mathrm{dm}^{-3}$ | 0.4 | 0 | 0 |
| $\therefore$ Equilibrium concentration $/ \mathrm{mol} \mathrm{dm}^{-3}$ | $-x$ | $(0.4-x)$ | $+x$ |
| $+x$ |  |  |  |
| C | $+x$ | $+x$ |  |

$$
\begin{gathered}
K_{b}=\frac{\left[\mathrm{NH}_{4}^{+}(\mathrm{aq})\right]\left[\mathrm{OH}^{-}(\mathrm{aq})\right]}{\left[\mathrm{NH}_{3}(\mathrm{aq})\right]}=1.80 \times 10^{-5} \\
\frac{(x)(x)}{(0.4-x)}=1.80 \times 10^{-5}
\end{gathered}
$$

Applying the approximation $0.40-x \sim 0.40$, we obtain

$$
\begin{aligned}
\frac{\left(x^{2}\right)}{0.4} & =1.80 \times 10^{-5} \\
x & =\left[\mathrm{OH}^{-}(\mathrm{aq})\right]=2.7 \times 10^{-3} \mathrm{~mol} \mathrm{dm}^{-3}
\end{aligned}
$$

Note: To test the approximation, $\left\{\left[2.7 \times 10^{-3}\right] / 0.4\right\} \times 100 \%=0.68 \%$, i.e. the assumption is valid.

$$
\therefore \mathrm{pOH}=-\log \left(2.7 \times 10^{-3}\right)=2.57
$$

Applying the relationship $\mathrm{pH}+\mathrm{pOH}=14.00$, we get

$$
\mathrm{pH}=14.00-2.57=11.43
$$

$$
\left(\text { or }\left[\mathrm{OH}^{-}(\mathrm{aq})\right]=\left(2.7 \times 10^{-3}\right), \therefore\left[\mathrm{H}^{+}(\mathrm{aq})\right]=10^{-14} / 2.7 \times 10^{-3}=3.7 \times 10^{-12} \therefore \mathrm{pH}=11.43\right)
$$

### 2.2.8 Relation between $K_{\mathrm{a}}$ and $K_{\mathrm{b}}$

$\boldsymbol{K}_{\mathrm{a}}$ and $\boldsymbol{K}_{\mathrm{b}}$ represent the strength of an acid and a base, respectively. In case of a conjugate acid-base pair, they are related in a simple manner so that if one is known, the other can be deduced. Consider the example:

$$
\begin{gathered}
\mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})+\mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq}) \\
K_{\mathrm{a}}=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]\left[\mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})\right]}{\left[\mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})\right]}
\end{gathered}
$$

The conjugate base, $\mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})$, reacts with water according to the equation

$$
\mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{OH}^{-}(\mathrm{aq})+\mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})
$$

The base ionization constant for the reaction,

$$
K_{\mathrm{b}}=\frac{\left[\mathrm{OH}^{-}(\mathrm{aq})\right]\left[\mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})\right]}{\left[\mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})\right]}
$$

Consider the product of these two ionization constants.

$$
\begin{gathered}
K_{\mathrm{a}} \times K_{\mathrm{b}}=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]\left[\mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})\right]}{\left[\mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})\right]} \times \frac{\left[\mathrm{OH}^{-}(\mathrm{aq})\right]\left[\mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})\right]}{\left[\mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})\right]} \\
K_{\mathrm{a}} \times K_{\mathrm{b}}=\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]\left[\mathrm{OH}^{-}(\mathrm{aq})\right] \\
\text { i.e. } \quad \boldsymbol{K}_{\mathrm{a}} \times \boldsymbol{K}_{\mathbf{b}}=\boldsymbol{K}_{\mathrm{w}}
\end{gathered}
$$

When the two reactions are added we see that it is simply the autoionization of water.

$$
\begin{aligned}
& \mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})+\mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq}) \quad----K_{\mathrm{a}} \\
& \mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{OH}^{-}(\mathrm{aq})+\mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})----K_{\mathrm{b}} \\
& \mathrm{H}_{2} \mathrm{O}(\mathrm{l})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})+\mathrm{OH}^{-}(\mathrm{aq}) \quad----K_{\mathrm{w}}
\end{aligned}
$$

This follows the general rule in chemical equilibrium as we have discussed earlier,
Note: If a reaction can be expressed as the sum of two or more reactions, the equilibrium constant for the overall reaction is given by the product of the equilibrium constants of the individual reactions.

Note that the relation $\boldsymbol{K}_{\mathrm{a}} \boldsymbol{K}_{\mathrm{b}}=\boldsymbol{K}_{\mathrm{w}}$ can also be obtained by considering the ionization of a weak base too.

From this we have $K_{\mathrm{a}} \times K_{\mathrm{b}}=K_{\mathrm{w}}$ and thus,

$$
K_{\mathrm{a}}=\frac{K_{\mathrm{w}}}{K_{\mathrm{b}}} \text { and } K_{\mathrm{b}}=\frac{K_{\mathrm{w}}}{K_{\mathrm{a}}}
$$

From this we can see that the stronger the acid (the larger $K_{\mathrm{a}}$ ), the weaker is the conjugate base (the smaller $K_{\mathrm{b}}$ ), and vice versa.

### 2.2.9 Hydrolysis of salts and the $\mathbf{p H}$ of their solutions

Salts formed by the reactions between acids and bases in definite proportions, undergo ionization in water. The cations/anions formed on ionization of salts either exist as hydrated ions in aqueous solutions or interact with water to reform corresponding acids/bases depending on the nature of salts. The process of interaction between water and cations/anions or both of salts is called hydrolysis. The pH of the solution gets affected by this interaction. The cations (e.g.: $\mathrm{Na}^{+}, \mathrm{K}^{+}, \mathrm{Ca}^{2+}, \mathrm{Ba}^{2+}$, etc.) of strong bases and anions (e.g.: $\mathrm{Cl}^{-}, \mathrm{Br}-, \mathrm{NO}_{3}^{-}, \mathrm{ClO}_{4}^{-}$etc.) of strong acids simply get hydrated but do not hydrolyse, and therefore the solutions of salts formed from strong acids and bases are neutral i.e., their pH is 7. For example;

$$
\mathrm{NaNO}_{3}(\mathrm{~s}) \rightarrow \mathrm{Na}^{+}(\mathrm{aq})+\mathrm{NO}_{3}^{-}(\mathrm{aq})
$$

However, the other categories of salts do undergo hydrolysis.
We now consider the hydrolysis of the salts of the following types:
(i) salts of a weak acid and a strong base, e.g.: $\mathrm{CH}_{3} \mathrm{COONa}$.
(ii) salts of a strong acid and a weak base, e.g.: $\mathrm{NH}_{4} \mathrm{Cl}$.
(iii) salts of a weak acid and a weak base, e.g.: $\mathrm{CH}_{3} \mathrm{COONH}_{4}$.

In the first case, $\mathrm{CH}_{3} \mathrm{COONa}$ being a salt of the weak acid $\mathrm{CH}_{3} \mathrm{COOH}$ and the strong base NaOH , gets completely ionised in aqueous solution.

$$
\mathrm{CH}_{3} \mathrm{COONa}(\mathrm{aq}) \rightarrow \mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})+\mathrm{Na}^{+}(\mathrm{aq})
$$

## G.C.E. (A/L) CHEMISTRY : UNIT 12

Acetate ion thus formed undergoes hydrolysis in water to give acetic acid and $\mathrm{OH}^{-}$ions

$$
\mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})+\mathrm{OH}^{-}(\mathrm{aq})
$$

Acetic acid being a weak acid ( $K_{\mathrm{a}}=1.8 \times 10^{-5}$ ) remains mainly unionized/undissociated in solution. This results in increase of $\mathrm{OH}^{-}$ion concentration in the solution making it basic. The pH of such a solution is more than 7 .

## Example 2.19

Calculate the pH of a $0.10 \mathrm{~mol} \mathrm{dm}{ }^{-3}$ solution of sodium acetate $\left(\mathrm{CH}_{3} \mathrm{COONa}\right)$. $K_{\mathrm{b}\left(\mathrm{CH}_{3} \mathrm{COO}^{-}\right)}=5.6 \times 10^{-10}$

## Answer

As $\mathrm{CH}_{3} \mathrm{COONa}$ completely ionizes into $\mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})$ and $\mathrm{Na}^{+}(\mathrm{aq})$ in solution, $\mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})$ ion undergoes hydrolysis.

|  | $\mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})+\mathrm{OH}^{-}(\mathrm{aq})$ |  |  |
| :--- | :---: | :---: | :---: |
| Initial concentration $/ \mathrm{mol} \mathrm{dm}^{-3}$ | 0.10 | 0 | 0 |
| Concentration change $/ \mathrm{mol} \mathrm{dm}^{-3}$ | $-x$ | $+x$ | $+x$ |
| $\therefore$ Equilibrium concentration $/ \mathrm{mol} \mathrm{dm}$ |  |  |  |
| $-x .10-x$ | $+x$ | $+x$ |  |

Now we can write the equilibrium constant for the hydrolysis or the base ionization constant as.

$$
K_{\mathrm{b}}=\frac{\left[\mathrm{OH}^{-}(\mathrm{aq})\right]\left[\mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})\right]}{\left[\mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})\right]}
$$

Substituting above values at equilibrium,

$$
K_{\mathrm{b}}=\frac{x^{2}}{(0.10-x)}=5.6 \times 10^{-10}
$$

Since $K_{\mathrm{b}}$ is very small and the initial concentration of the base is large, we can apply the approximation $0.10-x \sim 0.10$

$$
\begin{gathered}
\frac{x^{2}}{0.10} \sim 5.6 \times 10^{-10} \\
x^{2}=5.6 \times 10^{-11} \\
x=\left[\mathrm{OH}^{-}(\mathrm{aq})\right]=7.5 \times 10^{-6} \mathrm{~mol} \mathrm{dm}^{-3} \\
\therefore \mathrm{pOH}=5.13 \\
\mathrm{pH}=14.00-5.13=8.87
\end{gathered}
$$

Similarly, $\mathrm{NH}_{4} \mathrm{Cl}$ formed from the weak base, $\mathrm{NH}_{4} \mathrm{OH}$ and the strong acid, HCl , dissociates completely in water.

$$
\mathrm{NH}_{4} \mathrm{Cl}(\mathrm{aq}) \rightarrow \mathrm{NH}_{4}^{+}(\mathrm{aq})+\mathrm{Cl}^{-}(\mathrm{aq})
$$

Ammonium ions undergo hydrolysis with water to form $\mathrm{NH}_{4} \mathrm{OH}(\mathrm{aq})$ and $\mathrm{H}^{+}(\mathrm{aq})$ ions

$$
\mathrm{NH}_{4}^{+}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{NH}_{4} \mathrm{OH}(\mathrm{aq})+\mathrm{H}^{+}(\mathrm{aq})
$$

Ammonium hydroxide is a weak base ( $K_{\mathrm{b}}=1.77 \times 10^{-5}$ ) and therefore remains almost unionised in solution. This results in increase of $\mathrm{H}^{+}$ion concentration in solution making the solution acidic. Thus, the pH of $\mathrm{NH}_{4} \mathrm{Cl}$ solution in water is less than 7 .

Consider the hydrolysis of $\mathrm{CH}_{3} \mathrm{COONH}_{4}$ salt formed from a weak acid and a weak base. The ions formed undergo hydrolysis as follow:

$$
\mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})+\mathrm{NH}_{4}^{+}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})+\mathrm{NH}_{4} \mathrm{OH}(\mathrm{aq})
$$

$\mathrm{CH}_{3} \mathrm{COOH}$ and $\mathrm{NH}_{4} \mathrm{OH}$, also remain in partially dissociated form:

$$
\begin{aligned}
\mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq}) & \rightleftharpoons \mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})+\mathrm{H}^{+}(\mathrm{aq}) \\
\mathrm{NH}_{4} \mathrm{OH}(\mathrm{aq}) & \rightleftharpoons \mathrm{NH}_{4}^{+}(\mathrm{aq})+\mathrm{OH}^{-}(\mathrm{aq}) \\
\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) & \rightleftharpoons \mathrm{H}^{+}(\mathrm{aq})+\mathrm{OH}^{-}(\mathrm{aq})
\end{aligned}
$$

However, whether a solution containing such a salt is acidic, basic, or neutral depends on the relative strengths of the weak acid and the weak base. We can make qualitative predictions about these solutions as follows.

- $\quad K_{\mathrm{b}}>K_{\mathrm{a}}\left(\mathrm{p} K_{\mathrm{b}}<\mathrm{p} K_{\mathrm{a}}\right)$; i.e if $K_{b}$ for the anion is greater than $K_{\mathrm{a}}$ for the cation, then the solution must be basic because the anion will hydrolyze to a greater extent than the cation. At equilibrium, there will be more $\mathbf{O H}$ - ions than $\mathbf{H}^{+}$ ions.
- $\quad K_{\mathrm{b}}<K_{\mathrm{a}}\left(\mathrm{p} K_{\mathrm{b}}>\mathrm{p} K_{a}\right)$; i.e, if $K_{\mathrm{b}}$ for the anion is smaller than $K_{\mathrm{a}}$ for the cation, the solution will be acidic because cation hydrolysis will be more extensive than anion hydrolysis.
- $K_{\mathrm{a}} \sim K_{\mathrm{b}}\left(\mathrm{p} K_{\mathrm{b}} \sim \mathrm{p} K_{a}\right)$; If $K_{\mathrm{a}}$ is approximately equal to $K_{b}$, the solution will be nearly neutral.

### 2.2.10 Aqueous solutions containing a common ion

In previous sections in acid-base ionization and salt hydrolysis we have discussed the properties of solutions containing a single solute. In the solutions of two dissolved solutes containing the same ion or a common ion, properties will be different. A common ion suppresses the ionization of a weak acid or a weak base.

For example, when both sodium acetate and acetic acid are dissolved in the same solution, they both dissociate and ionize to produce $\mathrm{CH}_{3} \mathrm{COO}^{-}$ions as shown in the following equations where $\mathrm{CH}_{3} \mathrm{COONa}(\mathrm{aq})$ dissociates completely while $\mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})$ undergoes partial dissociation.

$$
\begin{gathered}
\mathrm{CH}_{3} \mathrm{COONa}(\mathrm{~s}) \rightarrow \mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})+\mathrm{Na}^{+}(\mathrm{aq}) \\
\mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})+\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})
\end{gathered}
$$

According to Le Chatelier's principle, the addition of $\mathrm{CH}_{3} \mathrm{COO}^{-}$ions from $\mathrm{CH}_{3} \mathrm{COONa}$ to a solution of $\mathrm{CH}_{3} \mathrm{COOH}$ will suppress the ionization of $\mathrm{CH}_{3} \mathrm{COOH}$ by shifting the equilibrium from right to left causing decrease in the hydrogen ion concentration. Therefore a solution containing both $\mathrm{CH}_{3} \mathrm{COOH}$ and $\mathrm{CH}_{3} \mathrm{COONa}$ will be less acidic than a solution containing only $\mathrm{CH}_{3} \mathrm{COOH}$ at the same concentration. The shift in equilibrium of the ionization of acetic acid is caused by the acetate ions from the salt. $\mathrm{CH}_{3} \mathrm{COO}^{-}$is the common ion because it is supplied by both $\mathrm{CH}_{3} \mathrm{COOH}$ and $\mathrm{CH}_{3} \mathrm{COONa}$.

The common ion effect is the shift in equilibrium caused by the addition of a compound having an ion in common with the dissolved substances.

The common ion effect plays an important role in determining the pH of a solution and the solubility of a slightly soluble salt.

Let us consider the pH of a solution containing a weak acid, HA, and a soluble salt of the weak acid, such as NaA.

$$
\begin{gathered}
\mathrm{HA}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})+\mathrm{A}^{-}(\mathrm{aq}) \\
K_{\mathrm{a}}=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]\left[\mathrm{A}^{-}(\mathrm{aq})\right]}{[\mathrm{HA}(\mathrm{aq})]}
\end{gathered}
$$

We can write,

$$
\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]=K_{\mathrm{a}} \frac{[\mathrm{HA}(\mathrm{aq})]}{\left[\mathrm{A}^{-}(\mathrm{aq})\right]}
$$

Taking - $\log$ on both sides,

$$
\begin{aligned}
-\log \left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right] & =-\log K_{\mathrm{a}}-\log \frac{[\mathrm{HA}(\mathrm{aq})]}{\left[\mathrm{A}^{-}(\mathrm{aq})\right]} \\
-\log \left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right] & =-\log K_{\mathrm{a}}+\log \frac{\left[\mathrm{A}^{-}(\mathrm{aq})\right]}{[\mathrm{HA}(\mathrm{aq})]}
\end{aligned}
$$

We can write,

$$
\begin{gathered}
\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}+\log \frac{\left[\mathrm{A}^{-}(\mathrm{aq})\right]}{[\mathrm{HA}(\mathrm{aq})]} \\
\text { or } \\
\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}+\log \frac{[\text { conjugate base }]}{[\text { acid }]}
\end{gathered}
$$

The above expression is called Henderson-Hasselbalch equation.
If we know $\boldsymbol{K}_{\mathrm{a}}$ and the concentrations of the acid and the salt of the acid, we can calculate the pH of the solution.

In problems that involve the common ion effect, we are usually given the starting concentrations of a weak acid HA and its salt, such as NaA. As long as the concentrations of these species are reasonably high $\left(0.10 \mathrm{~mol} \mathrm{dm}^{-3}\right)$, we can neglect the ionization of the acid and the hydrolysis of the salt. This is a valid approximation because HA is a weak acid and the extent of the hydrolysis of the $\mathrm{A}^{-}(\mathrm{aq})$ ion is generally very small. Moreover, the presence of common ion $\mathrm{A}^{-}(\mathrm{aq})$ from the salt NaA further suppresses the ionization of HA and the presence of unionized HA further suppresses the hydrolysis of $\mathrm{A}^{-}(\mathrm{aq})$. Thus we can use the starting concentrations as the equilibrium concentrations in the Henderson-Hasselbalch equation.

## Example 2.20

(i) Calculate the pH of a solution containing $0.20 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{CH}_{3} \mathrm{COOH}$ and $0.40 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{CH}_{3} \mathrm{COONa}$.
(ii) What would be the pH of a $0.20 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{CH}_{3} \mathrm{COOH}$ solution if no salt was present? $K_{\mathrm{a}\left(\mathrm{CH}_{3} \mathrm{COOH}\right)}=1.8 \times 10^{-5}$

## Answer

(i) $\mathrm{CH}_{3} \mathrm{COONa}(\mathrm{s})$ is a strong electrolyte and hence it dissociates completely giving $\left[\mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})\right]$ as $0.40 \mathrm{~mol} \mathrm{dm}{ }^{-3}$ and we can neglect the $\left[\mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})\right]$ from the $\mathrm{CH}_{3} \mathrm{COOH}$ acid as its dissociation is suppressed. Therefore, we can take $\left[\mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})\right]$ as $0.40 \mathrm{~mol} \mathrm{dm}{ }^{-3}$ and $\left[\mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})\right]$ as $0.20 \mathrm{~mol} \mathrm{dm}^{-3}$.

$$
\begin{gathered}
\mathrm{CH}_{3} \mathrm{COONa}(\mathrm{~s}) \rightarrow \mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})+\mathrm{Na}^{+}(\mathrm{aq}) \\
\mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})+\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq}) \\
0.20 \mathrm{~mol} \mathrm{dm}^{-3} \\
\mathrm{~mol} \mathrm{dm}^{-3} \\
K_{\mathrm{a}}=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]\left[\mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})\right]}{\left[\mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})\right]}=1.8 \times 10^{-5} \\
{\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]=\frac{(0.20)}{(0.40)} \times 1.8 \times 10^{-5}=9.0 \times 10^{-6} \mathrm{~mol} \mathrm{dm}^{-3}} \\
\mathrm{pH}=-\log \left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]=5.04
\end{gathered}
$$

or we can use

$$
\begin{gathered}
\mathrm{pH}=\mathrm{pK}_{\mathrm{a}}+\log \frac{\text { [conjugate base] }}{\text { [acid] }} \\
\mathrm{pH}=-\log \left(\mathrm{K}_{\mathrm{a}}\right)+\log \frac{\text { [conjugate base] }}{\text { [acid] }} \\
\mathrm{pH}=4.74+\log \frac{0.40}{0.20} \\
\mathrm{pH}=4.74+\log 2 \\
\mathrm{pH}=5.04
\end{gathered}
$$

## G.C.E. (A/L) CHEMISTRY: UNIT 12 Chemical Equilibrium

(ii) without common ion we have only the equilibrium of

|  | $\mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})+\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})$ |  |  |
| :--- | :---: | :--- | :--- |
| Initial concentration $/ \mathrm{mol} \mathrm{dm}$ |  |  |  |
| -3 | 0.20 | 0 | 0 |
| Concentration change $/ \mathrm{mol} \mathrm{dm}$ | $+x$ | $+x$ |  |
| $\therefore$ Equilibrium concentration $/ \mathrm{mol} \mathrm{dm}$ |  |  |  |
|  | $-x$ | $0.20-x$ | $+x$ |

Substituting with the assumption $0.20-x \sim 0.20$

$$
\begin{gathered}
K_{\mathrm{a}}=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]\left[\mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})\right]}{\left[\mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})\right]}=1.8 \times 10^{-5} \\
\frac{(x)^{2}}{0.20}=1.8 \times 10^{-5} \\
x=2 \times 10^{-3} \mathrm{~mol} \mathrm{dm}^{-3} \\
\therefore\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]=2 \times 10^{-3} \mathrm{~mol} \mathrm{dm}^{-3} \\
\mathrm{pH}=2.70
\end{gathered}
$$

This shows clearly that the presence of the common ion $\mathrm{CH}_{3} \mathrm{COO}^{-}$ suppresses the ionization of the acid $\mathrm{CH}_{3} \mathrm{COOH}$.

Following example shows an important situation, when the concentration of the acid and salt are the same.

## Example 2.21

Calculate the pH of a $1.0 \mathrm{dm}^{3}$ solution made by adding 0.10 mol of acetic acid and 0.10 mol of sodium acetate.

## Answer

In this case the $\left[\mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})\right]$ is the concentration of $\mathrm{CH}_{3} \mathrm{COONa}$ because it ionizes completely and therefore we can write:

| $\mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})+\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})$ |  |  |  |
| :---: | :---: | :---: | :---: |
| Initial concentration/ $\mathrm{mol} \mathrm{dm}{ }^{-3}$ | 0.10 | 0 | 0.10 |
| Change in concentration/ mol dm ${ }^{-3}$ | - $x$ | $+x$ | + $x$ |
| $\therefore$ Equilibrium concentration/ mol dm ${ }^{-3}$ | 0.10-x | $+x$ | $0.10+x$ |

$$
\begin{aligned}
K_{\mathrm{a}}= & \frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]\left[\mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})\right]}{\left[\mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})\right]}=1.8 \times 10^{-5} \\
& \frac{x(0.10+x)}{(0.10-x)}=1.8 \times 10^{-5}
\end{aligned}
$$

As $x$ is small, we can write,

$$
\begin{gathered}
\frac{x(0.10)}{(0.10)}=1.8 \times 10^{-5} \\
x=\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]=1.8 \times 10^{-5} \mathrm{~mol} \mathrm{dm}^{-3} \\
\therefore \mathrm{pH}=4.74 \\
\text { i. e. } \mathbf{p H}=\mathbf{p K}_{\mathrm{a}}
\end{gathered}
$$

The common ion effect also operates in a solution containing a weak base, such as $\mathrm{NH}_{3}$, and a salt of the base, say $\mathrm{NH}_{4} \mathrm{Cl}$. At equilibrium

$$
\begin{gathered}
\mathrm{NH}_{4} \mathrm{Cl}(\mathrm{aq}) \rightarrow \mathrm{NH}_{4}^{+}(\mathrm{aq})+\mathrm{Cl}^{-}(\mathrm{aq}) \\
\mathrm{NH}_{3}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})
\end{gathered} \stackrel{\mathrm{NH}_{4}^{+}(\mathrm{aq})+\mathrm{OH}^{-}(\mathrm{aq})}{ }
$$

Here, $\mathrm{NH}_{4}{ }^{+}(\mathrm{aq})$ is predominant over $\mathrm{NH}_{3}(\mathrm{aq})$ as it comes from the complete ionization of $\mathrm{NH}_{4} \mathrm{Cl}$ and hence the equilibrium $\mathrm{NH}_{3}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{NH}_{4}{ }^{+}(\mathrm{aq})+\mathrm{OH}^{-}(\mathrm{aq})$ is suppressed. Therefore, in this solution, pH is mainly controlled by the equilibrium

$$
\mathrm{NH}_{4}^{+}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{NH}_{3}(\mathrm{aq})+\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})
$$

We can write,

$$
\begin{gathered}
K_{\mathrm{a}}=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]\left[\mathrm{NH}_{3}(\mathrm{aq})\right]}{\left[\mathrm{NH}_{4}{ }^{+}(\mathrm{qq})\right]} \\
{\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]=\frac{K_{\mathrm{a}}\left[\mathrm{NH}_{4}{ }^{+}(\mathrm{aq})\right]}{\left[\mathrm{NH}_{3}(\mathrm{aq})\right]}} \\
-\log \left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]=-\log K_{\mathrm{a}}-\log \frac{\left[\mathrm{NH}_{4}^{+}(\mathrm{aq})\right]}{\left[\mathrm{NH}_{3}(\mathrm{aq})\right]} \\
-\log \left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]=
\end{gathered}-\log K_{\mathrm{a}}+\log \frac{\left[\mathrm{NH}_{3}(\mathrm{aq})\right]}{\left[\mathrm{NH}_{4}{ }^{+}(\mathrm{aq})\right]} .
$$

We can write

$$
\begin{gathered}
\mathrm{pH}=\mathrm{pK}_{\mathrm{a}}+\log \frac{\left[\mathrm{NH}_{3}(\mathrm{aq})\right]}{\left[\mathrm{NH}_{4}{ }^{+}(\mathrm{aq})\right]} \\
\mathrm{pH}=-\log \left(\mathrm{K}_{\mathrm{a}}\right)+\log \frac{[\text { conjugate base }]}{[\text { acid }]}
\end{gathered}
$$

A solution containing both $\mathrm{NH}_{3}$ and its salt $\mathrm{NH}_{4} \mathrm{Cl}$ is less basic than a solution containing only $\mathrm{NH}_{3}$ at the same concentration. The common ion $\mathrm{NH}_{4}{ }^{+}$suppresses the ionization of $\mathrm{NH}_{3}$ in the solution containing both the base and the salt.

### 2.2.11 Volumetric titrations

Titration is a procedure for determining the concentration of a solution using another solution of known concentration, called the standard solution. In this usually we perform the volume measurements and find the required volume of the one necessary to react completely with the other. The determination of the volume depends on the way we find the completion of the reaction.

## Equivalence points and end points

For a titration to be accurate we must add a stoichiometrically equivalent amount of the titrant (a solution with known concentration in a burette) to a solution containing the analyte (a solution with unknown concentration in a titration flask). We call the volume of the titrant required to reach this stoichiometric mixture the equivalence point, $\mathbf{V}_{\text {eq. }}$.

Knowing the stoichiometry of the titration reaction(s), we can calculate the amount of moles of the analyte. Unfortunately, in most titrations we usually have no obvious indication that the equivalence point has been reached. Instead, we stop adding titrant when we reach an end point of our choosing. Often this end point is indicated by a change in the color of a substance added to the solution containing the analyte. Such substances are known as indicators. Usually, indicators change their colour along with the change in pH of the solution, so that the volume of the titrant needed to reach the end point is little in excess compared to the equivalence point volume ( 1 drop of the titrant or $0.05 \mathrm{~cm}^{3}$ ). The difference between the end point and the equivalence point is called the titration error. Though the difference in volume is very small, we can see that this causes a significant change in pH . Hence the pH values at the end point and equivalence point are not comparable. In the case when we know the concentrations of both the titrant and the analyte, we can construct the pattern of change in a measured property (for example pH ) with the volume of the titrant and by this way the equivalence point is clearly defined. Following figures show the set-up of the titration and the comparison between equivalence and end points.

(a)

(b)

Figure 2.16
(a) A sketch of a titration set up: A solution with unknown concentration is placed in a titration flask and the solution is titrated against the tirant in the burette by adding it slowly. (b) shows the difference in end point and equivalence point where end point is determined by using an indicator in which we need some excess of the titrant $\quad\left(\sim 0.05 \mathrm{~cm}^{3}\right)$ to observe the colour change in the indicator. In the case of equivalnce point it is the point at which stoichiometric amounts are exacatly reacted. Therefore, equivalence point volume is always less than that of end point volume. This small difference in volumes, however, causes very large difference in pH .

## Acid-base titrations

Under this section, we will consider four types of titrations involving:
(i) a strong acid and a strong base,
(ii) a weak acid and a strong base,
(iii) a strong acid and a weak base, and
(iv) a weak acid and a weak base .

Titrations involving a weak acid and a weak base are complicated by the hydrolysis of both the cation and the anion of the salt formed.

In the following section, we will consider the above types of titrations with the understanding of their respective equivalence points and the variation and calculation of pH along the titration (along the volume of the titrant). It has to be noted that it is simply an understanding of pH variation theoretically by considering the titration between the analyte of known concentration and the titrant with a known concentration. With these considerations, we can construct the titration curves (volume $\boldsymbol{v s} \mathbf{p H}$ ) theoretically. i.e. A titration curve provides us with a visual picture of how a property, such as pH , changes as we add the titrant.

## - Strong acid - strong base titrations

Consider the titration of $25.00 \mathrm{~cm}^{3}$ of $0.100 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{HCl}$ with $0.100 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{NaOH}$.
(Note: The volumes are measured with burette and pipette with the accuracy of $0.00 \mathrm{~cm}^{3}$.)

Reaction taking place is,

$$
\mathrm{HCl}(\mathrm{aq})+\mathrm{NaOH}(\mathrm{aq}) \rightarrow \mathrm{NaCl}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

As $\mathrm{HCl}(\mathrm{aq}), \mathrm{NaOH}(\mathrm{aq})$ and $\mathrm{NaCl}(\mathrm{aq})$ are strong electrolytes, we can write the above reaction as,

$$
\mathrm{H}^{+}(\mathrm{aq})+\mathrm{Cl}^{-}(\mathrm{aq})+\mathrm{Na}^{+}(\mathrm{aq})+\mathrm{OH}^{-}(\mathrm{aq}) \rightarrow \mathrm{Na}^{+}(\mathrm{aq})+\mathrm{Cl}^{-}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

We can see that the pH of the solution depends on the relative concentrations of $\mathrm{H}^{+}(\mathrm{aq})$ and $\mathrm{OH}^{-}(\mathrm{aq})$ ions present at each stage of the volume of NaOH added and therefore it is possible to consider the situations like pH at the equivalence point, pH before the equivalence point, and pH after the equivalence point.

Let us first calculate the volume of NaOH needed to reach the equivalence point. At the equivalence point,
moles $\mathrm{HCl}=$ amount of moles NaOH (as the stoichiometry between HCl and NaOH is $1: 1$ )

Applying the simple formula $C_{\mathrm{a}} V_{\mathrm{a}}=C_{\mathrm{b}} V_{\mathrm{b}}$ where the subscript ' $a$ ' indicates the acid, HCl , and the subscript ' $b$ ' indicates the base, NaOH :
(i) The volume of NaOH needed to reach the equivalence point, therefore, is

$$
\begin{aligned}
& 0.100 \times 25.00=0.100 \times V_{\mathrm{b}} \\
& \therefore V_{\mathrm{b}}=25.00 \mathrm{~cm}^{3}
\end{aligned}
$$

(ii) Initially the solution is $0.100 \mathrm{~mol} \mathrm{dm}^{-3}$ in HCl . Since HCl is a strong acid, means that the pH is

$$
\mathrm{pH}=-\log \left[\mathrm{H}_{3} \mathrm{O}^{+}\right]=-\log [\mathrm{HCl}]=-\log (0.100)=1.00
$$

(iii)Before the equivalence point, HCl is present in excess and the pH is determined by the concentration of excess HCl . After adding $10.00 \mathrm{~cm}^{3}$ of NaOH , i.e. stoichiometrically lesser amount of NaOH compared to the amount of HCl present, the concentration of excess (or remaining) HCl has to be estimated.

## G.C.E. (A/L) CHEMISTRY: UNIT 12 Chemical Equilibrium

(iv) At the equivalence point (after addition of $25.00 \mathrm{~cm}^{3}$ of NaOH ) all the $\mathrm{H}^{+}$and $\mathrm{OH}^{-}$ ions are consumed. Also the salt NaCl present as $\mathrm{Na}^{+}$and $\mathrm{Cl}^{-}$does not undergo hydrolysis. Therefore, for the reaction of a strong base with a strong acid at the equivalence point the only equilibrium reaction (net reaction) of importance is,

$$
\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})+\mathrm{OH}^{-}(\mathrm{aq}) \rightleftharpoons 2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

At the equivalence point, $\left[\mathrm{H}^{+}(\mathrm{aq})\right]=\left[\mathrm{OH}^{-}(\mathrm{aq})\right]$ and the pH of the solution is 7.00.
(v) After adding $35.00 \mathrm{~cm}^{3}$ of NaOH , i.e. stoichiometrically higher amount of NaOH compared to the amount of HCl present, the concentration of excess (or remaining) NaOH has to be estimated.

Important: Now we can see that the pH curve has some deflection around $\mathrm{pH}=7$. Let's see the changes in pH in the vicinity of the equivalence point.

Addition of $24.90 \mathrm{~cm}^{3}$ of NaOH :
After adding $24.90 \mathrm{~cm}^{3}$ of NaOH , i.e. stoichiometrically lesser amount of NaOH compared to the amount of HCl present, the concentration of excess (or remaining) HCl has to be estimated.

$$
\begin{array}{ll}
\text { Initial amount of } \mathrm{HCl} \text { (in moles) } & =\frac{0.100 \mathrm{~mol}}{1.0 \mathrm{dm}^{3}} \times 25.00 \mathrm{~cm}^{3} \times \frac{1.0 \mathrm{dm}^{3}}{1000 \mathrm{~cm}^{3}} \\
& =2.50 \times 10^{-3} \mathrm{~mol} \\
\text { Amount of } \mathrm{NaOH} \text { added } & =\frac{0.100 \mathrm{~mol}^{1}}{1.0 \mathrm{dm}^{3}} \times 24.90 \mathrm{~cm}^{3} \times \frac{1.0 \mathrm{dm}^{3}}{1000 \mathrm{~cm}^{3}} \\
& =2.49 \times 10^{-3} \mathrm{~mol} \\
\therefore \text { Amount of } \mathrm{HCl} \text { reacted } & =2.49 \times 10^{-3} \mathrm{~mol} \\
\therefore \text { Amount of } \mathrm{HCl} \text { remaining } & =\left(2.50 \times 10^{-3}-2.49 \times 10^{-3}\right) \mathrm{mol} \\
& =1.00 \times 10^{-5} \mathrm{~mol} \\
\therefore \text { Concentration of } \mathrm{HCl}\left(\mathrm{H}_{3} \mathrm{O}^{+}\right) \text {remaining } & =\frac{1.00 \times 10^{-5} \mathrm{~mol}}{49.90 \mathrm{~cm}^{3}} \times \frac{1000 \mathrm{~cm}^{3}}{1.0 \mathrm{dm}^{3}} \\
& =2.00 \times 10^{-4} \mathrm{~mol} \mathrm{dm}^{-3}
\end{array}
$$

$$
\mathrm{pH}=-\log \left(2.00 \times 10^{-4}\right)=3.7
$$

Addition of $25.10 \mathrm{~cm}^{3}$ of NaOH :

| Initial amount of HCl (in moles) | $=\frac{0.100 \mathrm{~mol}}{1.0 \mathrm{dm}^{3}} \times 25.00 \mathrm{~cm}^{3} \times \frac{1.0 \mathrm{dm}^{3}}{1000 \mathrm{~cm}^{3}}$ |
| :--- | :--- |
|  | $=2.50 \times 10^{-3} \mathrm{~mol}$ |
| Amount of NaOH added | $=\frac{0.100 \mathrm{~mol}}{1.0 \mathrm{dm}^{3}} \times 25.10 \mathrm{~cm}^{3} \times \frac{1.0 \mathrm{dm}^{3}}{1000 \mathrm{~cm}^{3}}$ |
|  | $=2.51 \times 10^{-3} \mathrm{~mol}$ |
| $\therefore$ Amount of HCl reacted | $=2.50 \times 10^{-3} \mathrm{~mol}$ |
| $\therefore$ Amount of NaOH remaining | $=\left(2.51 \times 10^{-3}-2.50 \times 10^{-3}\right) \mathrm{mol}$ |
|  | $=1.0 \times 10^{-5} \mathrm{~mol}$ |
| $\therefore$ Concentration of $\mathrm{NaOH}\left(\mathrm{OH}^{-}\right)$remaining | $=\frac{1.0 \times 10^{-5} \mathrm{~mol}}{50.10 \mathrm{~cm}^{3}} \times \frac{1000 \mathrm{~cm}^{3}}{1.0 \mathrm{dm}^{3}}$ |
|  | $=2.00 \times 10^{-4} \mathrm{~mol} \mathrm{dm}^{-3}$ |
| $\therefore \mathrm{pOH}=-\log \left(2.00 \times 10^{-4}\right)=3.7$ |  |
| $\therefore \mathrm{pH}=14.00-3.70=10.30$ |  |

After addition of NaOH volumes higher than $25.00 \mathrm{~cm}^{3}$, i.e. stoichiometrically higher amount of NaOH compared to the amount of HCl present, the concentration of excess (or remaining) NaOH has to be estimated.

In this strong acid $v s$ strong base titration we can see that there is a drastic change in pH in the vicinity of the equivalence point $\left(6.6 \mathrm{pH}\right.$ unit change within the $0.020 \mathrm{~cm}^{3}$ volume interval). By plotting the calculated pH values against different volumes of NaOH added,
we can obtain the pH curve in Figure 2.17(a) and 2.17(b) shows the behaviour of pH curves with the variation of initial concentration of the acid and base.

Figure 2.17 (a) Titration curve for the titration of $25.00 \mathrm{~cm}^{3}$ of $0.100 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{HCl}$ with 0.100 $\mathrm{mol} \mathrm{dm}{ }^{-3} \mathrm{NaOH}$. A steep change in pH occurs in the vicinity of equivalence point at which $\mathrm{pH}=7.0$ with $25.00 \mathrm{~cm}^{3}$ of NaOH . (b) Shows the variation in pH curves with the initial concentrations of HCl and NaOH . When the initial concentration decreases the spread of the pH curve decreases. Role of indicators phenolphthalein and bromothymol blue will be discussed in a separate section.

## - Weak acid - strong base titrations

Consider the reaction between acetic acid (a weak acid) and sodium hydroxide (a strong base):

$$
\mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})+\mathrm{NaOH}(\mathrm{aq}) \rightarrow \mathrm{CH}_{3} \mathrm{COONa}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

As NaOH is a strong base we can rewrite the reaction as,

$$
\mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})+\mathrm{OH}^{-}(\mathrm{aq}) \rightarrow \mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

As we have discussed earlier, the $\mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})$ undergoes hydrolysis and the reaction will determine the pH at the equivalence point of the titration.

The acetate ion undergoes hydrolysis as follows:

$$
\mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})+\mathrm{OH}^{-}(\mathrm{aq})
$$

Therefore, at the equivalence point, where we have only sodium acetate, the pH will be greater than 7 as a result of the excess $\mathrm{OH}^{-}(\mathrm{aq})$ ions formed due to the hydrolysis of acetate ions. Let's try to understand the titration curve of this type of a titration where a weak acid is titrated with a strong base.

Consider the titration of $25.00 \mathrm{~cm}^{3}$ of $0.100 \mathrm{~mol} \mathrm{dm}{ }^{-3} \mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})$ with $0.100 \mathrm{~mol} \mathrm{dm} m^{-3} \mathrm{NaOH} . \quad K_{\mathrm{a}}\left(\mathrm{CH}_{3} \mathrm{COOH}\right)=1.80 \times 10^{-5}$

We can see that the pH of the solution depends on the relative concentrations of the undissociated $\mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})$ acid and $\mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})$ ions (formed as $\mathrm{CH}_{3} \mathrm{COONa}(\mathrm{aq})$ ) present) at each stage of the volume of NaOH added. Similar to the titration between a strong acid and a strong base, it is possible to consider the situations like pH at the equivalence point, pH before the equivalence point, and pH after the equivalence point.

Let us first calculate the volume of NaOH needed to reach the equivalence point. At the equivalence point,

Amount of moles $\mathrm{CH}_{3} \mathrm{COOH}=$ Amount of moles NaOH (as the stoichiometry between $\mathrm{CH}_{3} \mathrm{COOH}$ and NaOH is $1: 1$ )

Applying simple formula $C_{\mathrm{a}} V_{\mathrm{a}}=C_{\mathrm{b}} V_{\mathrm{b}}$
where the subscript ' $a$ ' indicates the acid, $\mathrm{CH}_{3} \mathrm{COOH}$, and the subscript ' $b$ ' indicates the base, NaOH .
(i) The volume of NaOH needed to reach the equivalence point, therefore, is

$$
\begin{aligned}
& 0.100 \times 25.00=0.100 \times V_{\mathrm{b}} \\
& \therefore V_{\mathrm{b}}=25.00 \mathrm{~cm}^{3}
\end{aligned}
$$

(ii) Initially the solution is $0.100 \mathrm{~mol} \mathrm{dm}^{-3}$ in $\mathrm{CH}_{3} \mathrm{COOH}$. Since $\mathrm{CH}_{3} \mathrm{COOH}$ is a weak acid, $\left[\mathrm{H}_{3} \mathrm{O}^{+}\right]$will be determined by its partial ionization, i.e

$$
\mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})+\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})
$$

[ $\mathrm{H}_{3} \mathrm{O}^{+}$] is calculated from $\boldsymbol{K}_{\mathrm{a}}$ as,

Initial concentration/ $\mathrm{mol} \mathrm{dm}{ }^{-3}$
Change in concentration/ $\mathrm{mol} \mathrm{dm}^{-3}$

$$
\mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})+\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})
$$

$\therefore$ Equilibrium concentration $/ \mathrm{mol} \mathrm{dm}^{-3}$

| 0.1 | 0 | 0 |
| :--- | :--- | :--- |
| $x$ | $+x$ | $+x$ |
| $(0.10-x)$ | $+x$ | $+x$ |

$$

where initail concentration of the acid is $C_{0}$

$$
\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]=\left(K_{\mathrm{a}} C_{0}\right)^{1 / 2}
$$

$$
-\log \left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]=-\log \left(K_{a}\right)^{\frac{1}{2}}-\log \left(C_{0}\right)^{\frac{1}{2}}
$$

$$
-\log \left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]=-\frac{1}{2} \log \left(K_{\mathrm{a}}\right)-\frac{1}{2} \log \left(C_{0}\right)
$$

$$
\mathrm{pH}=-\frac{1}{2} \mathrm{pK}_{\mathrm{a}}-\frac{1}{2} \log \left(C_{0}\right)
$$

(iii)Before the equivalence point, the added amount of NaOH is stoichiometrically lesser than the amount of $\mathrm{CH}_{3} \mathrm{COOH}$ acid present in the solution. Therefore, the solution contains undissociated $\mathrm{CH}_{3} \mathrm{COOH}$ acid and the salt $\mathrm{CH}_{3} \mathrm{COONa}$. In other words, now we have a mixture of a weak acid and its salt (conjugate base), i.e. a buffer solution. To calculate pH , we can use the Henderson-Hasselbalch equation with our knowledge of buffer solutions.

Let's consider the reaction after the addition of $10.00 \mathrm{~cm}^{3}$ of $0.100 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{NaOH}$.

$$
\mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})+\mathrm{NaOH}(\mathrm{aq}) \rightarrow \mathrm{CH}_{3} \mathrm{COONa}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

Initial amount of $\mathrm{CH}_{3} \mathrm{COOH}$

Amount of NaOH added

Amount of $\mathrm{CH}_{3} \mathrm{COOH}$ reacted
: Amount of $\mathrm{CH}_{3} \mathrm{COOH}$ remaining
Concentration of $\mathrm{CH}_{3} \mathrm{COOH}$ remaining
Amount of $\mathrm{CH}_{3} \mathrm{COONa}$ formed
Concentration of $\mathrm{CH}_{3} \mathrm{COONa}$ formed

$$
\begin{aligned}
& =\frac{0.100 \mathrm{~mol}^{1.0 \mathrm{dm}^{3}} \times 25.00 \mathrm{~cm}^{3} \times \frac{1.0 \mathrm{dm}^{3}}{1000 \mathrm{~cm}^{3}}}{=2.50 \times 10^{-3} \mathrm{~mol}} \\
& =\frac{0.100 \mathrm{~mol}^{1}}{1.0 \mathrm{dm}^{3}} \times 10.00 \mathrm{~cm}^{3} \times \frac{1.0 \mathrm{dm}^{3}}{1000 \mathrm{~cm}^{3}} \\
& =1.0 \times 10^{-3} \mathrm{~mol} \\
& =1.0 \times 10^{-3} \mathrm{~mol} \\
& =\left(2.50 \times 10^{-3}-1.00 \times 10^{-3}\right) \mathrm{mol} \\
& =1.50 \times 10^{-3} \mathrm{~mol} \\
& =\frac{1.5 \times 10^{-3} \mathrm{~mol}}{35.00 \mathrm{~cm}^{3}} \times \frac{1000 \mathrm{~cm}^{3}}{1.0 \mathrm{dm}^{3}} \\
& =0.043 \mathrm{~mol} \mathrm{dm}^{-3} \\
& =\text { Amount of NaOH added }=1.0 \times 10^{-3} \mathrm{~mol} \\
& =\frac{1.0 \times 10^{-3} \mathrm{~mol}_{3}^{35.00 \mathrm{~cm}^{3}} \times \frac{1000 \mathrm{~cm}^{3}}{1.0 \mathrm{dm}^{3}}}{=0.029 \mathrm{~mol} \mathrm{dm}^{-3}}
\end{aligned}
$$

Substituting these values in,

$$
\begin{gathered}
\mathrm{pH}=\mathrm{pK}_{\mathrm{a}}+\log \frac{\text { [conjugate base] }}{\text { [acid] }} \\
\mathrm{pH}=4.74+\log \frac{(0.029)}{(0.043)} \\
\mathrm{pH}=4.57
\end{gathered}
$$

## G.C.E. (A/L) CHEMISTRY: UNIT 12 Chemical Equilibrium

(iv) At the equivalence point (after addition of $25.00 \mathrm{~cm}^{3}$ of NaOH ) all the $\mathrm{CH}_{3} \mathrm{COOH}$ and NaOH are consumed. The salt $\mathrm{CH}_{3} \mathrm{COONa}$ present undergoes hydrolysis as,

$$
\mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})+\mathrm{OH}^{-}(\mathrm{aq})
$$

According to the reaction, $\mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})+\mathrm{NaOH}(\mathrm{aq}) \rightarrow \mathrm{CH}_{3} \mathrm{COONa}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})$
The amount of $\mathrm{CH}_{3} \mathrm{COONa}\left(\mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})\right)$ formed $=2.50 \times 10^{-3} \mathrm{~mol}$
$\therefore$ The concentration of the salt

$$
\begin{aligned}
& =\frac{2.5 \times 10^{-3} \mathrm{~mol}}{50.00 \mathrm{~cm}^{3}} \times \frac{1000 \mathrm{~cm}^{3}}{1.0 \mathrm{dm}^{3}} \\
& =0.05 \mathrm{~mol} \mathrm{dm}^{-3}
\end{aligned}
$$

|  | $\mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})$ | $\mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})$ | $+\mathrm{OH}^{-}(\mathrm{aq})$ |
| :---: | :---: | :---: | :---: |
| Initial concentration/ $\mathrm{mol} \mathrm{dm}^{-3}$ | 0.05 | 0 | 0 |
| Change in concentration/ mol dm ${ }^{-3}$ | -3 | + $x$ | + $x$ |
| $\therefore$ Equilibrium concentration/ $\mathrm{mol} \mathrm{dm}{ }^{-3}$ | (0.05-x) | $+x$ | + $x$ |
| $\therefore$ Equilibrium concentration/ $\mathrm{mol} \mathrm{dm}{ }^{-3}$ ) <br> (with the assumption $(0.05-x) \sim 0$ | $\begin{aligned} & 0.05 \\ & 0.05) \end{aligned}$ | + $x$ | + $x$ |

For the above hydrolysis reaction we can write the expression for $\boldsymbol{K}_{\mathbf{b}}$ as,

$$
\begin{gathered}
K_{\mathrm{b}}=\frac{\left[\mathrm{OH}^{-}(\mathrm{aq})\right]\left[\mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})\right]}{\left[\mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})\right]}=\frac{x^{2}}{(0.05)}=\frac{K_{\mathrm{w}}}{K_{\mathrm{a}}}=5.6 \times 10^{-10} \\
x=\left[\mathrm{OH}^{-}(\mathrm{aq})\right]=5.3 \times 10^{-6} \mathrm{~mol} \mathrm{dm}^{-3} \\
\therefore \mathrm{pOH}=5.28 \\
\therefore \mathrm{pH}=14.00-5.28 \\
\therefore \mathrm{pH}=8.72
\end{gathered}
$$

$o r$,

$$
\begin{gathered}
\boldsymbol{K}_{\mathrm{b}}=\frac{\left[\mathrm{OH}^{-}(\mathrm{aq})\right]\left[\mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})\right]}{\left[\mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})\right]} \\
\boldsymbol{K}_{\mathrm{b}}=\frac{\left[\mathrm{OH}^{-}(\mathrm{aq})\right]^{2}}{\boldsymbol{S}}
\end{gathered}
$$

where $S$ is the concentration of the salt

$$
\left[\mathrm{OH}^{-}(\mathrm{aq})\right]=\left(\boldsymbol{K}_{\mathrm{b}} S\right)^{1 / 2}
$$

$$
-\log \left[\mathrm{OH}^{-}(\mathrm{aq})\right]=-\log \left(K_{\mathrm{b}}\right)^{\frac{1}{2}}-\log (S)^{\frac{1}{2}}
$$

$$
-\log \left[\mathrm{OH}^{-}(\mathrm{aq})\right]=-\frac{1}{2} \log \left(K_{\mathrm{b}}\right) \quad-\frac{1}{2} \log S
$$

$$
\mathrm{pOH}=-\frac{1}{2} \mathrm{p} K_{\mathrm{b}}-\frac{1}{2} \log S
$$

Substituting, $\quad \mathrm{pH}+\mathrm{pOH}=\mathrm{p} K_{\mathrm{w}}$ and $\mathrm{p} K_{\mathrm{a}}+\mathrm{p} K_{\mathrm{b}}=\mathrm{p} K_{\mathrm{w}}$

$$
\begin{gathered}
\mathrm{p} K_{\mathrm{w}}-\mathrm{pH}=-\frac{1}{2}\left(\mathrm{p} K_{\mathrm{w}}-\mathrm{p} K_{\mathrm{a}}\right)-\frac{1}{2} \log S \\
\therefore \mathrm{pH}=\frac{1}{2} \mathrm{p} K_{\mathrm{a}}+\frac{1}{2} \mathrm{p} K_{\mathrm{w}}+\frac{1}{2} \log S
\end{gathered}
$$

## G.C.E. (A/L) CHEMISTRY: UNIT 12 Chemical Equilibrium

(v) After the equivalence point the total amount of $\mathrm{CH}_{3} \mathrm{COOH}$ initially present gets converted to the salt $\mathrm{CH}_{3} \mathrm{COONa}$ and excess NaOH will present as $\mathrm{OH}^{-}$. Therefore, the pH of the mixture is determined by the excess concentration of [ $\left.\mathrm{OH}^{-}(\mathrm{aq})\right]$.

After adding $35.00 \mathrm{~cm}^{3}$ of NaOH , i.e. stoichiometrically higher amount of NaOH compared to the amount of $\mathrm{CH}_{3} \mathrm{COOH}$ present, the concentration of excess (or remaining) NaOH has to be estimated.

| Initial amount of $\mathrm{CH}_{3} \mathrm{COOH}$ | $=\frac{0.100 \mathrm{~mol}}{1.0 \mathrm{dm}^{3}} \times 25.00 \mathrm{~cm}^{3} \times \frac{1.0 \mathrm{dm}^{3}}{1000 \mathrm{~cm}^{3}}$ |
| :--- | :--- |
|  | $=2.50 \times 10^{-3} \mathrm{~mol}$ |
| Amount of NaOH added | $=\frac{0.100 \mathrm{~mol}^{1.0} \mathrm{dm}^{3}}{} \times 35.00 \mathrm{~cm}^{3} \times \frac{1.0 \mathrm{dm}^{3}}{1000 \mathrm{~cm}^{3}}$ |
|  | $=3.50 \times 10^{-3} \mathrm{~mol}$ |
| $\therefore$ Amount of $\mathrm{CH}_{3} \mathrm{COOH}$ reacted | $=2.5 \times 10^{-3} \mathrm{~mol}$ |
| $\therefore$ Amount of NaOH remaining | $=\left(3.50 \times 10^{-3}-2.50 \times 10^{-3}\right) \mathrm{mol}$ |
|  | $=1.0 \times 10^{-3} \mathrm{~mol}$ |
| $\therefore$ Concentration of $\mathrm{NaOH}\left(\mathrm{OH}^{-}\right)$remaining | $=\frac{1.0 \times 10^{-3} \mathrm{~mol}}{60.00 \mathrm{~cm}^{3}} \times \frac{1000 \mathrm{~cm}^{3}}{1.0 \mathrm{dm}^{3}}$ |
|  | $=0.017 \mathrm{~mol} \mathrm{dm}^{-3}$ |

$\therefore \mathrm{pOH}=-\log (0.017)=1.77$
$\mathrm{pH}=14.00-1.77=12.23$
Or, After the equivalence point, $\quad\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]=\frac{\boldsymbol{K}_{\mathrm{w}}}{\left[\mathrm{OH}^{-}(\mathrm{aq})\right]}$

$$
\left[\mathrm{OH}^{-}(\mathrm{aq})\right] \text { is the excess concentration of the strong base }
$$

And taking excess $\left[\mathrm{OH}^{-}(\mathrm{aq})\right]=\boldsymbol{B}^{\prime}$

$$
\begin{gathered}
{\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]=\frac{\boldsymbol{K}_{\mathrm{w}}}{\boldsymbol{B}^{\prime}}} \\
-\log \left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]=-\log \left(\boldsymbol{K}_{\mathbf{w}}\right)-\left(-\log \boldsymbol{B}^{\prime}\right) \\
\mathbf{p H}=\mathbf{p} K_{\mathrm{w}}+\log \left(\boldsymbol{B}^{\prime}\right)
\end{gathered}
$$

At the half-equivalence point:

$$
\mathrm{p} H=\mathrm{p} K_{a}+\log \frac{\text { [conjugate base] }}{[\text { acid }]}
$$

Concentrations of the acid and the conjugate base are equal.

$$
\therefore \mathrm{pH}=\mathrm{p} K_{\mathrm{a}}
$$

We can summarize the above in the following pH curve in Figure 2.18.

Figure 2.18 (a) Titration curve for the titration of $25.00 \mathrm{~cm}^{3}$ of $0.100 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{CH}_{3} \mathrm{COOH}$ with $0.100 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{NaOH}$. Equivalnvce point occurs in basic region with pH of 8.72. In these titrations a buffer solution is formed below the equivalence point (will be explained in a separate section 12.3). Charateristics points with the pH functions are also marked. In (b) variations of pH curves with the strength of the weak acid are compared. Weaker the acid, the equivalence point shifts more to the basic side.

- Strong acid - weak base titrations

Let us consider the titration between $\mathrm{NH}_{3}$, a weak base and HCl , a strong acid: the reaction taking place is;

$$
\mathrm{HCl}(\mathrm{aq})+\mathrm{NH}_{3}(\mathrm{aq}) \rightarrow \mathrm{NH}_{4} \mathrm{Cl}(\mathrm{aq})
$$

or simply

$$
\mathrm{H}^{+}(\mathrm{aq})+\mathrm{NH}_{3}(\mathrm{aq}) \rightarrow \mathrm{NH}_{4}^{+}(\mathrm{aq})
$$

We can see that the pH at the equivalence point is less than 7 due to the hydrolysis of the $\mathrm{NH}_{4}{ }^{+}(\mathrm{aq})$

$$
\mathrm{NH}_{4}^{+}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{NH}_{3}(\mathrm{aq})+\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})
$$

Because of the volatility of an aqueous ammonia solution, it is more convenient to add HCl acid from a burette to the ammonia solution.

## Example:

Let $25.00 \mathrm{~cm}^{3}$ of $0.10 \mathrm{~mol} \mathrm{dm}{ }^{-3} \mathrm{NH}_{3}$, a weak base be titrated with $0.10 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{HCl}$, a strong acid.

We can see that the pH of the solution depends on the relative concentrations of the undissociated $\mathrm{NH}_{4} \mathrm{Cl}$ and $\mathrm{NH}_{3}$ at each stage of the volume of HCl added. Therefore, like the case considered for the weak acid-strong base titration, it is possible to consider pH at the equivalence point, pH before the equivalence point, and pH after the equivalence point.

Let us first calculate the volume of HCl needed to reach the equivalence point. At the equivalence point,

Amount of moles of $\mathrm{NH}_{3}=$ Amount of moles of HCl (as the stoichiometry between $\mathrm{NH}_{3}$ and HCl is $1: 1$ )

Applying the formula $C_{\mathrm{a}} V_{\mathrm{a}}=C_{\mathrm{b}} V_{\mathrm{b}}$
(i) The volume of HCl needed to reach the equivalence point, therefore, is

$$
\begin{aligned}
& 0.100 \times 25.00=0.100 \times V_{\mathrm{b}} \\
& \therefore V_{\mathrm{b}}=25.00 \mathrm{~cm}^{3}
\end{aligned}
$$

(ii) Initially the solution is $0.100 \mathrm{~mol} \mathrm{dm}^{-3}$ in $\mathrm{NH}_{3}$. Since $\mathrm{NH}_{3}$ is a weak base, $\left[\mathrm{OH}^{-}\right]$ will be determined considering its partial ionization, i.e

$$
\mathrm{NH}_{3}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{NH}_{4}^{+}(\mathrm{aq})+\mathrm{OH}^{-}(\mathrm{aq})
$$

$\left[\mathrm{OH}^{-}\right]$is calculated from $\boldsymbol{K}_{\mathbf{b}}$ as,

|  | $\mathrm{NH}_{3}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons$ | $\mathrm{NH}_{4}^{+}(\mathrm{aq})+\mathrm{OH}^{-}(\mathrm{aq})$ |
| :---: | :---: | :---: |
| Initial concentration/ $\mathrm{mol} \mathrm{dm}^{-3}$ | 0.1 | $0 \quad 0$ |
| Change in concentration/ $\mathrm{mol} \mathrm{dm}{ }^{-3}$ | -x | $+x+x$ |
| $\therefore$ Equilibrium concentration/ $\mathrm{mol} \mathrm{dm}^{-3}$ | (0.10-x) | $+x \quad+x$ |
| $\therefore$ Equilibrium concentration/ $\mathrm{mol} \mathrm{dm}^{-3}$ | 0.10 | $+x+x$ |

(with the assumption $(0.10-x) \sim 0.1$ )

$$
\begin{gathered}
K_{\mathrm{b}}=\frac{\left[\mathrm{NH}_{4}^{+}(\mathrm{aq})\right]\left[\mathrm{OH}^{-}(\mathrm{aq})\right]}{\left[\mathrm{NH}_{3}(\mathrm{aq})\right]}=\frac{x^{2}}{(0.1)}=1.80 \times 10^{-5} \\
x^{2}=1.80 \times 10^{-6} \\
x=1.34 \times 10^{-3} \\
\mathrm{pOH}=-\log \left[\mathrm{OH}^{-}(\mathrm{aq})\right]=-\log \left[1.34 \times 10^{-3}\right]=2.87 \\
\therefore \mathrm{pH}=14.00-2.87=11.13
\end{gathered}
$$

(iii)Before the equivalence point, the added amount of HCl is stoichiometrically lesser than the amount of $\mathrm{NH}_{3}$ present in the solution. Therefore, the solution contains undissociated $\mathrm{NH}_{3}$ and the salt $\mathrm{NH}_{4} \mathrm{Cl}$. In other words, now we have a mixture of a

## G.C.E. (A/L) CHEMISTRY: UNIT 12 Chemical Equilibrium

weak base and its salt (conjugate acid), i.e. a buffer solution. To calculate pH , we can use our knowledge of buffer solutions.

Let's consider the reaction after the addition of $10.00 \mathrm{~cm}^{3}$ of $0.100 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{HCl}$.

$$
\mathrm{HCl}(\mathrm{aq})+\mathrm{NH}_{3}(\mathrm{aq}) \rightarrow \mathrm{NH}_{4} \mathrm{Cl}(\mathrm{aq})
$$

Initial amount of $\mathrm{NH}_{3}$

$$
\begin{aligned}
& =\frac{0.100 \mathrm{~mol}^{1.0 \mathrm{dm}^{3}} \times 25.00 \mathrm{~cm}^{3} \times \frac{1.0 \mathrm{dm}^{3}}{1000 \mathrm{~cm}^{3}}}{=2.50 \times 10^{-3} \mathrm{~mol}} \\
& =\frac{0.100 \mathrm{~mol}^{1.0} \mathrm{dm}^{3}}{} \times 10.00 \mathrm{~cm}^{3} \times \frac{1.0 \mathrm{dm}^{3}}{1000 \mathrm{~cm}^{3}}
\end{aligned}
$$

Amount of HCl added

$$
\begin{aligned}
& =\frac{0.100 \mathrm{~mol}_{1}^{1.0 \mathrm{~m}^{3}} \times 10.00 \mathrm{~cm}^{3} \times \frac{1.0 \mathrm{dm}^{3}}{1000 \mathrm{~cm}^{3}}}{=1.0 \times 10^{-3} \mathrm{~mol}} \\
& =1.0 \times 10^{-3} \mathrm{~mol} \\
& =\left(2.50 \times 10^{-3}-1.00 \times 10^{-3}\right) \mathrm{mol} \\
& =1.50 \times 10^{-3} \mathrm{~mol} \\
& =\frac{1.5 \times 10^{-3} \mathrm{~mol}^{3}}{35.00 \mathrm{~cm}^{3}} \times \frac{1000 \mathrm{~cm}^{3}}{1.0 \mathrm{dm}^{3}} \\
& =0.043 \mathrm{~mol} \mathrm{dm}^{-3}
\end{aligned}
$$

Amount of $\mathrm{NH}_{3}$ reacted
Amount of $\mathrm{NH}_{3}$ remaining

Concentration of $\mathrm{NH}_{3}$ remaining $=\frac{1.5 \times 10^{-3} \mathrm{~mol}^{-3}}{35.00 \mathrm{~cm}^{3}} \times \frac{1000 \mathrm{~cm}^{3}}{1.0 \mathrm{dm}^{3}}$

Amount of $\mathrm{NH}_{4} \mathrm{Cl}$ formed $=$ Amount of HCl added $=1.0 \times 10^{-3} \mathrm{~mol}$
Concentration of $\mathrm{NH}_{4} \mathrm{Cl}$ formed $\quad=\frac{1.0 \times 10^{-3} \mathrm{~mol}}{35.00 \mathrm{~cm}^{3}} \times \frac{1000 \mathrm{~cm}^{3}}{1.0 \mathrm{dm}^{3}}=0.029 \mathrm{~mol} \mathrm{dm}^{-3}$
Substituting these values in,

$$
\begin{gathered}
\mathrm{pOH}=\mathrm{pK}_{\mathrm{b}}+\log \frac{\text { [conjugate base] }}{[\text { acid }]} \\
\mathrm{pOH}=4.74+\log \frac{(0.029)}{(0.043)} \\
\mathrm{pOH}=4.57 \\
\therefore \mathrm{pH}=14.00-4.57=9.43
\end{gathered}
$$

(iv) At the equivalence point (after addition of $25.00 \mathrm{~cm}^{3}$ of HCl ) all the $\mathrm{NH}_{3}$ and HCl are consumed. The salt $\mathrm{NH}_{4} \mathrm{Cl}$ present undergoes hydrolysis as,

$$
\mathrm{NH}_{4}^{+}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{NH}_{3}(\mathrm{aq})+\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})
$$

According to the reaction, $\mathrm{HCl}(\mathrm{aq})+\mathrm{NH}_{3}(\mathrm{aq}) \rightarrow \mathrm{NH}_{4} \mathrm{Cl}(\mathrm{aq})$
The amount of $\mathrm{NH}_{4} \mathrm{Cl}\left(\mathrm{NH}_{4}^{+}(\mathrm{aq})\right)$ formed $=2.50 \times 10^{-3} \mathrm{~mol}$
$\therefore$ The concentration of the salt $=\frac{2.5 \times 10^{-3} \mathrm{~mol}^{5}}{50.00 \mathrm{~cm}^{3}} \times \frac{1000 \mathrm{~cm}^{3}}{1.0 \mathrm{dm}^{3}}=0.05 \mathrm{~mol} \mathrm{dm}^{-3}$

| $\mathrm{NH}_{4}{ }^{+}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})$ | $\rightleftharpoons \mathrm{NH}_{3}(\mathrm{aq})$ | $+\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})$ |
| :--- | :---: | :---: |
| 0.05 | 0 | 0 |
| $-x$ | $+x$ | $+x$ |
| $(0.05-x)$ | $+x$ | $+x$ |
| 0.05 | $+x$ | $+x$ |

Initial concentration/ $\mathrm{mol} \mathrm{dm}^{-3}$
Change in concentration/ $\mathrm{mol} \mathrm{dm}^{-3}$
$\therefore$ Equilibrium concentration/ $\mathrm{mol} \mathrm{dm}^{-3}$
(0.05-x) $+x+x$
$\therefore$ Equilibrium concentration $/ \mathrm{mol} \mathrm{dm}^{-3}$
0.05
$+x \quad+x$
(with the assumption ( $0.05-x$ ) $\sim 0.05$ )

## G.C.E. (A/L) CHEMISTRY : UNIT 12 Chemical Equilibrium

For the above hydrolysis reaction we can write the expression for $\boldsymbol{K}_{b}$ as,

$$
\begin{gathered}
K_{\mathrm{b}}=\frac{\left[\mathrm{NH}_{3}(\mathrm{aq})\right]\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]}{\left[\mathrm{NH}_{4}^{+}(\mathrm{aq})\right]} \\
5.6 \times 10^{-10}=\frac{x^{2}}{0.05}(\text { with the assumption }) \\
x^{2}=28 \times 10^{-12} \\
x=\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]=5.3 \times 10^{-6} \\
\therefore \mathrm{pH}=5.28
\end{gathered}
$$

(v) After the equivalence point the total amount of $\mathrm{NH}_{3}$ initially present gets converted to the salt $\mathrm{NH}_{4} \mathrm{Cl}$ and excess HCl will be present as $\mathrm{H}_{3} \mathrm{O}^{+}$. Therefore, the pH of the mixture is determined by the excess concentration of $\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]$.

In order to calculate pH after adding $35.00 \mathrm{~cm}^{3}$ of HCl , i.e. stoichiometrically a higher amount of HCl compared to the amount of $\mathrm{NH}_{3}$ present, the concentration of excess (or remaining) HCl has to be estimated.
Initial amount of $\mathrm{NH}_{3}$

$$
\begin{aligned}
& =\frac{0.100 \mathrm{~mol}}{1.0 \mathrm{dm}^{3}} \times 25.00 \mathrm{~cm}^{3} \times \frac{1.0 \mathrm{dm}^{3}}{1000 \mathrm{~cm}^{3}} \\
& =2.50 \times 10^{-3} \mathrm{~mol} \\
& =\frac{0.100 \mathrm{~mol}^{1}}{1.0 \mathrm{dm}^{3}} \times 35.00 \mathrm{~cm}^{3} \times \frac{1.0 \mathrm{dm}^{3}}{1000 \mathrm{~cm}^{3}} \\
& =3.50 \times 10^{-3} \mathrm{~mol} \\
& =2.5 \times 10^{-3} \mathrm{~mol} \\
& =\left(3.50 \times 10^{-3}-2.50 \times 10^{-3}\right) \mathrm{mol} \\
& =1.0 \times 10^{-3} \mathrm{~mol}
\end{aligned}
$$

Amount of HCl added

Amount of $\mathrm{NH}_{3}$ reacted
Amount of HCl remaining
Concentration of $\mathrm{HCl}\left(\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right)$ remaining $=\frac{1.0 \times 10^{-3} \mathrm{~mol}}{60.00 \mathrm{~cm}^{3}} \times \frac{1000 \mathrm{~cm}^{3}}{1.0 \mathrm{dm}^{3}}$

$$
=0.017 \mathrm{~mol} \mathrm{dm}^{-3}
$$

$\therefore p H=-\log (0.017)=1.77$

Figure 2.19 (a) Titration curve for the titration of $25.00 \mathrm{~cm}^{3}$ of $0.100 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{NH}_{3}$ with $0.100 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{HCl}$. Equivalnvce point occurs in acidic region with pH of 5.28. In these titrations a buffer solution is formed too below the equivalence point. In (b) variations of pH curves with the strength of the weak base are compared. Weaker the base, the equivalence point shifts more to acidic side.

## - Weak acid- weak base titration

When acetic acid, which is a weak acid, reacts with ammonia, the reaction taking place is,

$$
\mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})+\mathrm{NH}_{3}(\mathrm{aq}) \rightarrow \mathrm{NH}_{4}{ }^{+}(\mathrm{aq})+\mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})
$$

Now we can see that the products contain the base $\mathrm{CH}_{3} \mathrm{COO}^{-}$and the acid $\mathrm{NH}_{4}{ }^{+}$. Therefore, the pH at the equivalence point id determined by the strength of the hydrolysis of these. We can write,

$$
\begin{gathered}
\mathrm{NH}_{4}{ }^{+}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{NH}_{3}(\mathrm{aq})+\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq}): \boldsymbol{K}_{\mathrm{a}} \\
\mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})+\mathrm{OH}^{-}(\mathrm{aq}): \boldsymbol{K}_{\mathbf{b}}
\end{gathered}
$$

From these reactions, we see that $\mathrm{H}_{3} \mathrm{O}^{+}$and $\mathrm{OH}^{-}$ions are formed and they undergo neutralization. Though neutralization occurs, still we may not have equal amount of $\mathrm{H}_{3} \mathrm{O}^{+}$ and $\mathrm{OH}^{-}$and hence $\mathrm{pH} \neq 7$ at the equivalence point. It depends on the relative strengths of $K_{\mathrm{a}}$ and $K_{\mathrm{b}}$ : if $K_{\mathrm{a}}>K_{\mathrm{b}}$, the solution is acidic and if $K_{\mathrm{a}}<K_{\mathrm{b}}$, the solution is basic .

Another important feature in this kind of a titration is that there is no steep pH changing region in the pH curve and it mainly shows a deflecting point, resulting in difficulty to use an indicator to locate the equivalence point. Therefore, the titrations between a weak acid and a weak base are hardly carried out. Figure 2.20 shows the variation of pH in this type of a titration.

## G.C.E. (A/L) CHEMISTRY : UNIT 12 Chemical Equilibrium

Note: It has to be noted that the pH of such solutions is determined by using pK values of the acid and the base using the mathematical formula,

$$
\mathrm{pH}=7+1 / 2\left(\mathrm{p} K_{\mathrm{a}}-\mathrm{p} K_{\mathrm{b}}\right)
$$

The pH of the solution can be greater than 7 , if the difference is positive and it will be less than 7 , if the difference is negative.

Figure 2.20 Titration curve for the titration of $25.00 \mathrm{~cm}^{3}$ of $0.100 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{CH}_{3} \mathrm{COOH}$ with $0.100 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{NH}_{3}$. It is difficult to judge to location of the equivalence point as it depends on the relative strengths of the acid and the base. There is no steep change in pH in these types of systems.

Figure 2.21 Summary of the four types of titrations with $0.100 \mathrm{~mol} \mathrm{dm}^{-3}$ acid (mono basic) and $0.100 \mathrm{~mol} \mathrm{dm}^{-3}$ base (mono acidic) discussed above. (SA-strong acid, SB-strong base, WA-Weak acid and WB-Weak base)

### 2.2.12 Di - and polybasic acids and di- and polyacidic bases

Some of the acids like oxalic acid $\left(\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}\right)$, sulphuric acid $\left(\mathrm{H}_{2} \mathrm{SO}_{4}\right)$ and phosphoric acid $\left(\mathrm{H}_{3} \mathrm{PO}_{4}\right)$ have more than one ionizable proton per molecule of the acid. Such acids are known as polybasic or polyprotic acids. The ionization reactions of a dibasic acid $\mathrm{H}_{2} \mathrm{~A}$ are represented by the equations:

$$
\begin{aligned}
\mathrm{H}_{2} \mathrm{~A}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) & \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})+\mathrm{HA}^{-}(\mathrm{aq}) \\
\mathrm{HA}^{-}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) & \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})+\mathrm{A}^{2-}(\mathrm{aq})
\end{aligned}
$$

And the corresponding equilibrium constants (acid ionization constants) are given below:

$$
\begin{aligned}
K_{\mathrm{a}_{1}} & =\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]\left[\mathrm{HA}^{-}(\mathrm{aq})\right]}{\left[\mathrm{H}_{2} \mathrm{~A}(\mathrm{aq})\right]} \\
K_{\mathrm{a}_{2}} & =\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]\left[\mathrm{A}^{2-}(\mathrm{aq})\right]}{\left[\mathrm{HA}^{-}(\mathrm{aq})\right]}
\end{aligned}
$$

Likewise, the ionization reactions of a diacidic base $\mathrm{B}_{2}{ }^{-}$are represented by the equations:

$$
\begin{aligned}
& \mathrm{B}^{2-}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{HBB}^{-}(\mathrm{aq})+\mathrm{OH}^{-}(\mathrm{aq}) \\
& \mathrm{HB}^{-}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{H}_{2} \mathrm{~B}(\mathrm{aq})+\mathrm{OH}^{-}(\mathrm{aq})
\end{aligned}
$$

And the corresponding equilibrium constants (base ionization constants) are given below:

$$
\begin{aligned}
& K_{\mathrm{b}_{1}}=\frac{\left[\mathrm{HB}^{-}(\mathrm{aq})\right]\left[\mathrm{OH}^{-}(\mathrm{aq})\right]}{\left[\mathrm{B}^{2-}(\mathrm{aq})\right]} \\
& K_{\mathrm{b}_{2}}\left.=\frac{\left[\mathrm{H}_{2} \mathrm{~B}(\mathrm{aq})\right][\mathrm{OH}}{}{ }^{-}(\mathrm{aq})\right] \\
& {\left[\mathrm{HB}^{-}(\mathrm{aq})\right] }
\end{aligned}
$$

## Polyacidic base titrations

The pH curve for the titration of hydrochloric acid with sodium hydroxide has only one equivalence (end) point (Figure 2.17), but the pH curve for the addition of $\mathrm{HCl}(\mathrm{aq})$ (titrant) to $\mathrm{Na}_{2} \mathrm{CO}_{3}(\mathrm{aq})$ (Figure 2.22) displays two equivalence points, i.e. two rapid change in pH . Here, for example, two successive reactions occur. The two end points in Figure 2.22 can be explained by two different proton transfer equations.

Sodium carbonate is a strong electrolyte and so fully dissociates into $\mathrm{Na}^{+}(\mathrm{aq})$ and $\mathrm{CO}_{3}{ }^{2-}(\mathrm{aq})$ ions.

$$
\mathrm{Na}_{2} \mathrm{CO}_{3}(\mathrm{aq}) \rightarrow \mathrm{Na}^{+}(\mathrm{aq})+\mathrm{CO}_{3}{ }^{2-}(\mathrm{aq})
$$

Therefore, the major entities in the mixture are $\mathrm{Na}^{+}(\mathrm{aq}), \mathrm{CO}_{3}{ }^{2-}(\mathrm{aq})$ and $\mathrm{H}_{2} \mathrm{O}(\mathrm{l})$. At the beginning of the titration, $\mathrm{H}^{+}(\mathrm{aq})$ ions from $\mathrm{HCl}(\mathrm{aq})$ react with $\mathrm{CO}_{3}{ }^{2-}(\mathrm{aq})$ ions since carbonate ions are the strongest bases present in the initial mixture.

$$
\mathrm{H}^{+}(\mathrm{aq})+\mathrm{CO}_{3}{ }^{2-}(\mathrm{aq}) \rightarrow \mathrm{HCO}_{3}^{-}(\mathrm{aq})
$$

Then, in a second reaction, protons from $\mathrm{HCl}(\mathrm{aq})$ react with the hydrogen carbonate ions formed in the first reaction.

$$
\mathrm{H}^{+}(\mathrm{aq})+\mathrm{HCO}_{3}^{-}(\mathrm{aq}) \rightarrow \mathrm{H}_{2} \mathrm{CO}_{3}(\mathrm{aq})
$$

It is clear that at the first equivalence point, following equilibrium exists in the mixture and therefore the pH is determined by the hydrolysis of $\mathrm{HCO}_{3}^{-}(\mathrm{aq})$ ions.

$$
\mathrm{HCO}_{3}^{-}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{H}_{2} \mathrm{CO}_{3}(\mathrm{aq})+\mathrm{OH}^{-}(\mathrm{aq})
$$

At the second equivalence point following equilibrium exists in the mixture and therefore the pH is determined by the hydrolysis (first ionization) of $\mathrm{H}_{2} \mathrm{CO}_{3}(\mathrm{aq})$ acid.

$$
\mathrm{H}_{2} \mathrm{CO}_{3}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{HCO}_{3}^{-}(\mathrm{aq})+\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})
$$

By looking at the above two reactions one may note that; at the first equivalence point mixture is basic while it becomes acidic at the second equivalence point.

## Example:

Let's consider a titration of $25.00 \mathrm{~cm}^{3}$ of $0.10 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{Na}_{2} \mathrm{CO}_{3}(\mathrm{aq})$ solution with $0.10 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{HCl}(\mathrm{aq})$ acid. Acid dissociation constants for the carbonic acid, $\mathrm{H}_{2} \mathrm{CO}_{3}$ are $K_{\mathrm{a}_{1}}=4.3 \times 10^{-7} \mathrm{~mol} \mathrm{dm}^{-3}$ and $K_{\mathrm{a}_{2}}=4.7 \times 10^{-11} \mathrm{~mol} \mathrm{dm}^{-3}$.

From the molarities of the solutions, one can note that the first equivalence point occurs at $25.00 \mathrm{~cm}^{3}$ and the second equivalence point occurs at the $50.00 \mathrm{~cm}^{3}$ of HCl .

When we consider the dissociation of $\mathrm{H}_{2} \mathrm{CO}_{3}$ acid:

$$
\begin{aligned}
\mathrm{H}_{2} \mathrm{CO}_{3}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) & \rightleftharpoons \mathrm{HCO}_{3}^{-}(\mathrm{aq})+\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq}): K_{\mathrm{a}_{1}} \\
\mathrm{HCO}_{3}^{-}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) & \rightleftharpoons \mathrm{CO}_{3}^{2-}(\mathrm{aq})+\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq}): K_{\mathrm{a}_{2}}
\end{aligned}
$$

Therefore,

$$
\begin{aligned}
& K_{\mathrm{a}_{1}}=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]\left[\mathrm{HCO}_{3}^{-}(\mathrm{aq})\right]}{\left[\mathrm{H}_{2} \mathrm{CO}_{3}(\mathrm{aq})\right]}=4.3 \times 10^{-7} \mathrm{~mol} \mathrm{dm}^{-3} \\
& K_{\mathrm{a}_{2}}=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]\left[\mathrm{CO}_{3}{ }^{2-}(\mathrm{aq})\right]}{\left[\mathrm{HCO}_{3}{ }^{-}(\mathrm{aq})\right]}=4.7 \times 10^{-11} \mathrm{~mol} \mathrm{dm}
\end{aligned}
$$

Initial pH (at $0.00 \mathrm{~cm}^{3}$ of HCl ):
At this point as no acid has been added, and only $0.10 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{Na}_{2} \mathrm{CO}_{3}(\mathrm{aq})$ sodium carbonate solution is present. The pH is determined by the extent of carbonate ion reaction with water to give $\mathrm{HCO}_{3}^{-}(\mathrm{aq})$ and $\mathrm{OH}^{-}(\mathrm{aq})$.

## G.C.E. (A/L) CHEMISTRY: UNIT 12 Chemical Equilibrium

$$
\mathrm{CO}_{3}^{2-}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{HCO}_{3}^{-}(\mathrm{aq})+\mathrm{OH}^{-}(\mathrm{aq})
$$

Here water acts as an acid, providing a proton to carbonate ion, the base. The equilibrium constant for this reaction can be written as;

$$
K^{\prime}=\frac{\left[\mathrm{HCO}_{3}^{-}(\mathrm{aq})\right]\left[\mathrm{OH}^{-}(\mathrm{aq})\right]}{\left[\mathrm{CO}_{3}{ }^{2-}(\mathrm{aq})\right]}
$$

Consider; $\frac{K_{\mathrm{w}}}{\mathrm{Ka}_{2}}=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]\left[0 \mathrm{H}^{-}(\mathrm{aq})\right]}{\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]\left[\mathrm{CO}_{3}{ }^{2-}(\mathrm{aqq})\right]}{\left[\mathrm{HCO}_{3}{ }^{-}(\mathrm{aq})\right]}}=\frac{\left[\mathrm{HCO}_{3}{ }^{-}(\mathrm{aq})\right]\left[0 \mathrm{H}^{-}(\mathrm{aq})\right]}{\left[\mathrm{CO}_{3}{ }^{2-}(\mathrm{aq})\right]}=K^{\prime}=K_{\mathrm{b}_{1}}$

$$
\begin{gathered}
\therefore K_{\mathrm{b}_{1}}=\frac{1.0 \times 10^{-14} \mathrm{~mol}^{2} \mathrm{dm}^{-6}}{4.7 \times 10^{-11} \mathrm{~mol} \mathrm{dm}^{-3}}=2.13 \times 10^{-4} \mathrm{~mol} \mathrm{dm}^{-3} \\
\begin{aligned}
\therefore K_{\mathrm{b}_{1}}= & \frac{\left[\mathrm{OH}^{-}(\mathrm{aq})\right]^{2}}{\left[\mathrm{CO}_{3}^{2-(\mathrm{aq})]}\left(\mathrm{as}\left[\mathrm{HCO}_{3}^{-}(\mathrm{aq})\right]=\left[\mathrm{OH}^{-}(\mathrm{aq})\right]\right)\right.} \\
{\left[\mathrm{OH}^{-}(\mathrm{aq})\right]^{2}=} & K_{\mathrm{b}_{1}}\left[\mathrm{CO}_{3}^{2-}(\mathrm{aq})\right]=2.13 \times 10^{-4} \mathrm{~mol} \mathrm{dm}^{-3} \times 0.10 \mathrm{~mol} \mathrm{dm}^{-3} \\
= & 2.13 \times 10^{-5} \mathrm{~mol} \mathrm{dm}^{-3}
\end{aligned} \\
\therefore\left[\mathrm{OH}^{-}(\mathrm{aq})\right]=4.61 \times 10^{-3} \mathrm{~mol} \mathrm{dm}^{-3} \\
{\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]=2.2 \times 10^{-12} \mathrm{~mol} \mathrm{dm}^{-3}} \\
\therefore \mathrm{pH}=11.71
\end{gathered}
$$

First equivalence point $S$ (at $25.00 \mathrm{~cm}^{3}$ of HCl ):
As previously explained, at the first equivalence point equilibrium existing is;

$$
\begin{equation*}
\mathrm{HCO}_{3}^{-}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{H}_{2} \mathrm{CO}_{3}(\mathrm{aq})+\mathrm{OH}^{-}(\mathrm{aq}) \tag{1}
\end{equation*}
$$

For the above equilibrium we can write,

$$
K=\frac{\left[\mathrm{H}_{2} \mathrm{CO}_{3}(\mathrm{aq})\right]\left[\mathrm{OH}^{-}(\mathrm{aq})\right]}{\left[\mathrm{HCO}_{3}^{-}(\mathrm{aq})\right]}
$$

This $K$ has a direct relationship with the $K_{\mathrm{a}_{1}}$ of carbonic acid as,

$$
K=\frac{K_{\mathrm{w}}}{K_{\mathrm{a}_{1}}}=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]\left[\mathrm{OH}^{-}(\mathrm{aq})\right]}{\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]\left[\mathrm{HCO}_{3}^{-}(\mathrm{aq})\right]}{\left[\mathrm{H}_{2} \mathrm{CO}_{3}(\mathrm{aq})\right]}}=\frac{\left[\mathrm{H}_{2} \mathrm{CO}_{3}(\mathrm{aq})\right]\left[\mathrm{OH}^{-}(\mathrm{aq})\right]}{\left[\mathrm{HCO}_{3}^{-}(\mathrm{aq})\right]}=K_{\mathrm{b}_{2}}
$$

$K_{\mathrm{b}_{2}}$ is the second ionization constant of $\mathrm{CO}_{3}{ }^{2-}(\mathrm{aq})$ as we can write,

$$
\begin{aligned}
& \mathrm{CO}_{3}^{2-}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{HCO}_{3}^{-}(\mathrm{aq})+\mathrm{OH}^{-}(\mathrm{aq}): K_{\mathrm{b}_{1}} \\
& \mathrm{HCO}_{3}^{-}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{H}_{2} \mathrm{CO}_{3}(\mathrm{aq})+\mathrm{OH}^{-}(\mathrm{aq}): K_{\mathrm{b}_{2}}
\end{aligned}
$$

## G.C.E. (A/L) CHEMISTRY: UNIT 12 Chemical Equilibrium

$$
\therefore K_{\mathrm{b}_{2}}=\frac{\left[\mathrm{H}_{2} \mathrm{CO}_{3}(\mathrm{aq})\right]\left[\mathrm{OH}^{-}(\mathrm{aq})\right]}{\left[\mathrm{HCO}_{3}^{-}(\mathrm{aq})\right]}=\frac{1.0 \times 10^{-14} \mathrm{~mol}^{2} \mathrm{dm}^{-6}}{4.3 \times 10^{-7} \mathrm{~mol} \mathrm{dm}^{-3}}=2.33 \times 10^{-8} \mathrm{~mol} \mathrm{dm}^{-3}
$$

For the reaction (1),

$$
\begin{gathered}
\mathrm{HCO}_{3}^{-}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{H}_{2} \mathrm{CO}_{3}(\mathrm{aq})+\mathrm{OH}^{-}(\mathrm{aq}) \\
K_{\mathrm{b}_{2}}=\frac{\left[\mathrm{H}_{2} \mathrm{CO}_{3}(\mathrm{aq})\right]\left[\mathrm{OH}^{-}(\mathrm{aq})\right]}{\left[\mathrm{HCO}_{3}^{-}(\mathrm{aq})\right]}
\end{gathered}
$$

At equilibrium:

$$
K_{\mathrm{b}_{2}}=\frac{\left[\mathrm{OH}^{-}(\mathrm{aq})\right]^{2}}{\left[\mathrm{HCO}_{3}^{-}(\mathrm{aq})\right]} \quad\left(\mathrm{as}\left[\mathrm{H}_{2} \mathrm{CO}_{3}(\mathrm{aq})\right]=\left[\mathrm{OH}^{-}(\mathrm{aq})\right]\right)
$$

As the first equivalence point occurs at $25.00 \mathrm{~cm}^{3}$ of HCl ;

$$
\begin{gathered}
{\left[\mathrm{HCO}_{3}^{-}(\mathrm{aq})\right]=\frac{0.10 \mathrm{~mol} \mathrm{dm}}{}{ }^{-3} \times 25.00 \times 10^{-3} \mathrm{dm}^{3}} \\
50.00 \times 10^{-3} \mathrm{dm}^{3}=0.05 \mathrm{~mol} \mathrm{dm}^{-3} \\
\therefore\left[\mathrm{OH}^{-}(\mathrm{aq})\right]^{2}=K_{\mathrm{b}_{2}}\left[\mathrm{HCO}_{3}^{-}(\mathrm{aq})\right]=2.33 \times 10^{-8} \mathrm{~mol} \mathrm{dm}^{-3} \times 0.05 \mathrm{~mol} \mathrm{dm}^{-3} \\
\therefore\left[\mathrm{OH}^{-}(\mathrm{aq})\right]=3.4 \times 10^{-5} \mathrm{~mol} \mathrm{dm}^{-3} \\
{\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]=2.9 \times 10^{-10} \mathrm{~mol} \mathrm{dm}^{-3}} \\
\therefore \mathbf{p H}=\mathbf{9 . 4 7}
\end{gathered}
$$

Second equivalence point ( at $50.00 \mathrm{~cm}^{3}$ of HCl ):
As previously explained, at the second equivalence point equilibrium exist is;

$$
\begin{equation*}
\mathrm{H}_{2} \mathrm{CO}_{3}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{HCO}_{3}^{-}(\mathrm{aq})+\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq}) \tag{2}
\end{equation*}
$$

For the above equilibrium we can write;

$$
\begin{aligned}
& K^{\prime}=\frac{\left[\mathrm{HCO}_{3}^{-}(\mathrm{aq})\right]\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]}{\left[\mathrm{H}_{2} \mathrm{CO}_{3}(\mathrm{aq})\right]}=K_{\mathrm{a}_{1}}=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]^{2}}{\left[\mathrm{H}_{2} \mathrm{CO}_{3}(\mathrm{aq})\right]} \\
& \left(\mathrm{as}\left[\mathrm{H}_{2} \mathrm{CO}_{3}(\mathrm{aq})\right]=\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]\right)
\end{aligned}
$$

To reach the second equivalence point after the first equivalence point another $25.00 \mathrm{~cm}^{3}$ of HCl is needed. Therefore, $\left[\mathrm{H}_{2} \mathrm{CO}_{3}(\mathrm{aq})\right]$ at the second equivalence point can be calculated as follows.

$$
\left.\begin{array}{c}
{\left[\mathrm{H}_{2} \mathrm{CO}_{3}(\mathrm{aq})\right]=\frac{0.10 \mathrm{~mol} \mathrm{dm}^{-3} \times 25.00 \times 10^{-3} \mathrm{dm}^{3}}{75.00 \times 10^{-3} \mathrm{dm}^{3}}=0.03 \mathrm{~mol} \mathrm{dm}^{-3}} \\
{\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]^{2}=K_{\mathrm{a}_{1}}\left[\mathrm{H}_{2} \mathrm{CO}_{3}(\mathrm{aq})\right]}
\end{array} \mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]^{2}=4.3 \times 10^{-7} \mathrm{~mol} \mathrm{dm}{ }^{-3} \times 0.03 \mathrm{~mol} \mathrm{dm}^{-3}=1.3 \times 10^{-8} \mathrm{~mol}^{2} \mathrm{dm}^{-6}{ }^{\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]=1.14 \times 10^{-4} \mathrm{~mol} \mathrm{dm}^{-3}} \begin{gathered}
\therefore \mathbf{p H}=3.94
\end{gathered}
$$

According to above findings the pH at the first equivalence point is 9.4 and that at the second equivalence point it is $\sim 4.0$. Therefore, it is clear that in an experiment, the first equivalence point can be detected by phenolphthalein indictor while methyl orange is suitable to detect the second equivalence point. Figure 2.22 shows the variation of pH during the titration.

Figure 2.22 Titration curve for the titration of $25.00 \mathrm{~cm}^{3}$ of $0.100 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{Na}_{2} \mathrm{CO}_{3}$ with $0.100 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{HCl}$. There are two equivalence points: first is due to the reaction of $\mathrm{CO}_{3}{ }^{2-}$ with HCl to form $\mathrm{HCO}_{3}{ }^{-}$and the second one is due to the conversion of $\mathrm{HCO}_{3}{ }^{-}$to $\mathrm{H}_{2} \mathrm{CO}_{3}$.

### 2.2.13 Acid-base indicators

In the previous section, we discussed the equivalence point of a titration of an acid and a base, as the point at which the number of moles of $\mathrm{OH}^{-}$ions added to a solution is equal to the number of moles of $\mathrm{H}^{+}$ions originally present. To determine the equivalence point in a titration, then, we must know exactly what volume of a solution of a base has to be added from a burette to an acid in a flask. One way to achieve this goal is to add a few drops of a foreign substance called an acid-base indicator to the acid solution at the start of the titration.

## Finding the end point with an indicator

One interesting group of these indicators is weak acids and bases which are derivatives of organic dyes. Because such compounds have at least one conjugate acid-base species that is highly coloured, their use in a titration results in a change in colour with the change in pH . This change in colour can serve as a useful means for determining the end point of a titration, provided that it occurs at the titration's equivalence point. Indicator has distinctly different colours in its non-ionized and ionized forms. These two forms are related to the pH of the solution in which the indicator is dissolved. The pH at which an
acid-base indicator changes colour is determined by its acid dissociation constant. For an indicator that is a monoprotic weak acid, HIn, the following dissociation reaction occurs.

$$
\mathrm{HIn}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})+\mathrm{In}^{-}(\mathrm{aq})
$$

for which the equilibrium constant is,

$$
K_{\mathrm{In}}=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]\left[\mathrm{In}^{-}(\mathrm{aq})\right]}{[\mathrm{HIn}(\mathrm{aq})]}
$$

Taking the negative $\log$ of each side of equation and rearranging to solve for pH gives a familiar equation.

$$
\begin{gathered}
-\log \left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]=-\log K_{\mathrm{In}}+\log \frac{\left[\ln ^{-}(\mathrm{aq})\right]}{[\mathrm{HIn}(\mathrm{aq})]} \\
\mathrm{pH}=\mathrm{p} K_{\mathrm{In}}+\log \frac{\left[\operatorname{In}^{-}(\mathrm{aq})\right]}{[\operatorname{HIn}(\mathrm{aq})]}
\end{gathered}
$$

The two forms of the indicator, HIn and $\mathrm{In}^{-}$, have different colours. The colour of a solution containing an indicator, therefore, continuously changes as the concentration of HIn decreases and the concentration of $\mathrm{In}^{-}$increases. If we assume that both HIn and $\mathrm{In}^{-}$ can be detected with equal ease, then the transition between the two colours reaches its midpoint when their concentrations are identical or when the $\mathbf{p H}$ is equal to the indicator's $\mathbf{p} \boldsymbol{K}_{\text {In }}$. The equivalence point and the end point coincide, therefore, if an indicator is selected whose $\mathbf{p} K_{\text {In }}$ is equal to the pH at the equivalence point, and the titration is continued until the indicator's colour is exactly halfway between that for HIn and $\mathrm{In}^{-}$.

Unfortunately, the exact pH at the equivalence point is rarely known. In addition, detecting the point where the concentrations of HIn and $\mathrm{In}^{-}$are equal may be difficult if the change in colour is subtle. We can establish a range of $\mathbf{p H s}$ within which we can observe a change in colour of the indicator if we assume that a solution of the indicator is the colour of HIn whenever its concentration is ten times more than that of $\mathrm{In}^{-}$, and the colour of $\mathrm{In}^{-}$whenever the concentration of HIn is ten times less than that of $\mathrm{In}^{-}$.
i.e. If the indicator is in a sufficiently acidic medium, the equilibrium, according to Le Chatelier's principle, shifts to the left and the predominant colour of the indicator is that of the nonionized form (HIn). On the other hand, in a basic medium the equilibrium shifts to the right and the colour of the solution will be due mainly to that of the conjugate base $\left(\mathrm{In}^{-}\right)$. Therefore, we can use the following concentration ratios to predict the perceived colour of the indicator:

When,

$$
\frac{[\mathrm{HIn}(\mathrm{aq})]}{\left[\operatorname{In}^{-}(\mathrm{aq})\right]} \geq 10
$$

$$
\begin{gathered}
\mathrm{pH}=\mathrm{p} K_{\text {In }}+\log \frac{1}{10} \\
\mathrm{pH}=\mathrm{p} K_{\text {In }}-1
\end{gathered}
$$

$\therefore$ color of HIn acid predominates
When,

$$
\begin{gathered}
\frac{\left[\mathrm{In}^{-}(\mathrm{aq})\right]}{[\operatorname{HIn}(\mathrm{aq})]} \geq 10 \\
\mathrm{pH}=\mathrm{p} K_{\mathrm{In}}+\log \frac{10}{1} \\
\mathrm{pH}=\mathrm{p} K_{\mathrm{In}}+1
\end{gathered}
$$

color of $\mathrm{In}^{-}$conjugate base predominates

Figure 2.23 Behaviour of an indicator: $\mathrm{HIn}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})+\operatorname{In}^{-}(\mathrm{aq})$
The end point of an indicator does not occur at a specific pH ; rather, there is a range of pH within which the end point will occur. In practice, we choose an indicator whose end point lies on the steep part of the titration curve. Because the equivalence point also lies on the steep part of the curve, this choice ensures that the pH at the equivalence point will fall within the range over which the indicator changes colour. For example, phenolphthalein is a suitable indicator for the titration of NaOH and HCl . Phenolphthalein is colourless in acidic and neutral solutions, but reddish pink in basic solutions. Measurements show that at $\mathrm{pH}=8.3$ the indicator is colourless but that it begins to turn reddish pink when the pH exceeds 8.3. As shown in Figure 2.22, the steepness of the pH curve near the equivalence point means that the addition of a very small quantity of NaOH $\left(\sim 0.05 \mathrm{~cm}^{3}\right)$ brings about a large rise in the pH of the solution. What is important, however, is the fact that the steep portion of the pH profile includes the range over which phenolphthalein changes from colourless to reddish pink. Whenever such a correspondence occurs, the indicator can be used to locate the equivalence point of the titration.

Table 2.4 Some common acid-base indicators

| Indicator | Colour in acid | Colour in base | $\mathbf{p H}$ range | $\mathbf{p} \boldsymbol{K}_{\text {In }}$ |
| :--- | :--- | :--- | :--- | :--- |
| Thymol blue | Red | Yellow | $1.2-2.8$ | 1.7 |
| Bromophenol blue | Yellow | Purple | $3.0-4.6$ | 4.1 |
| Methyl orange | Orange | Yellow | $3.1-4.4$ | 3.7 |
| Methyl red | Red | Yellow | $4.2-6.3$ | 5.0 |
| Chlorophenol red | Yellow | Red | $5.2-6.8$ | 6.0 |
| Bromothymol blue | Yellow | Blue | $6.0-7.6$ | 7.1 |
| Cresol red | Yellow | Red | $7.2-8.8$ | 8.2 |
| Phenolphthalein | Colorless | Reddish pink | $8.3-10.0$ | 9.6 |

Figure 2.24 Colour changing pH ranges for some indicators

## Selection of an indicator for a titration

The relatively broad range of pHs over which any indicator changes colour places additional limitations on the feasibility of a titration. To minimize a titration error or to conduct the titration with acceptable high accuracy, an indicator's entire colour transition must lie within the sharp transition in pH occurring near the equivalence point. Thus, in Figure 2.25 (a) we see that phenolphthalein is an appropriate indicator for the titration of $0.1 \mathrm{~mol} \mathrm{dm}^{-3}$ acetic acid with $0.1 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{NaOH}$. Methyl red, on the other hand, is an
inappropriate indicator since its change in colour begins before the initial sharp rise in pH and, as a result, spans a relatively large range of volumes. The early change in color increases the probability of obtaining inaccurate results, and the range of possible end point volumes increases the probability of obtaining imprecise results. Figure 2.25 (b) shows that for a titration of $0.1 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{HCl}$ acid with $0.1 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{NaOH}$ i.e. strong acid vs strong base titration, both phenolphthalein and methyl red can be used as the indicator.

Figure 2.25 Selection of an appropriate indicator for a given titration. In the case of weak acid-strong base titration phenolphthalein is a sutable indicator. Methyl orange indicator has no colour changing pH range in the equivalence point pH changing range as shown in (a). As shown in (b) both the indicators can be used for the titration between a strong acid and a strong base.

### 2.3 Buffer solutions

From a simple experiment we can observe that adding as little as $0.10 \mathrm{~cm}^{3}$ of concentrated HCl to a $1.0 \mathrm{dm}^{3}$ of $\mathrm{H}_{2} \mathrm{O}$ shifts the pH from 7.0 to 3.0. Also the addition of about $0.10 \mathrm{~cm}^{3}$ of concentrated NaOH to a $1.0 \mathrm{dm}^{3}$ of $\mathrm{H}_{2} \mathrm{O}$ shifts the pH from 7.0 to 11.0 . However, the same addition of either HCl or NaOH to a solution that is $0.10 \mathrm{~mol} \mathrm{dm}^{-3}$ in both a weak acid and its conjugate weak base, results in only a negligible change in pH . Such solutions are called buffers, and their buffering action is a consequence of the relationship between pH and the relative concentrations of the conjugate weak acid/weak base pair.
i.e. A buffer solution is a solution of a weak acid or a weak base and its salt. The solution has the ability to resist changes in pH upon the addition of small amounts of either acid or base.
Or

#### Abstract

A buffer solution is a solution containing a conjugate weak acid/weak base pair that is resistant to a change in pH when small volumes of a strong acid or a strong base are added.

According to above definition, a buffer solution must contain a relatively large concentration of acid to react with any $\mathrm{OH}^{-}$ions that are added to it, and it must contain a similar concentration of base to react with any added $\mathrm{H}^{+}$ions. The acid and the base components of the buffer must not consume each other in a neutralization reaction. These requirements are satisfied by an acid-base conjugate pair, for example, a weak acid and its conjugate base (supplied by a salt) or a weak base and its conjugate acid (supplied by a salt). Buffer solutions of known pH can be prepared from the knowledge of $\mathbf{p} \boldsymbol{K}$ a of the acid or $\mathbf{p} \boldsymbol{K}_{\mathbf{b}}$ of base and by controlling the ratio of the salt and acid or salt and base. A mixture of acetic acid and sodium acetate acts as buffer solution around pH 4.75 and a mixture of ammonium chloride and ammonium hydroxide act as a buffer around pH 9.25 . Let us consider a buffer solution prepared by adding comparable amounts of acetic acid $\left(\mathrm{CH}_{3} \mathrm{COOH}\right)$ and its salt sodium acetate $\left(\mathrm{CH}_{3} \mathrm{COONa}\right)$ to water. The equilibrium concentrations of both the acid and the conjugate base (from $\mathrm{CH}_{3} \mathrm{COONa}$ ) are assumed to be the same as the starting concentrations as the presence of a common ion suppresses the dissociation of a weak acid/base. A solution containing these two substances has the ability to neutralize either added acid or added base. In the solution $\mathrm{CH}_{3} \mathrm{COONa}$, a strong electrolyte, dissociates completely in water:

$$
\mathrm{CH}_{3} \mathrm{COONa}(\mathrm{aq}) \rightarrow \mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})+\mathrm{Na}^{+}(\mathrm{aq})
$$

If an acid is added, the $\mathrm{H}^{+}$ions will be consumed by the conjugate base in the buffer, $\mathrm{CH}_{3} \mathrm{COO}^{-}$, according to the equation:

$$
\mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})+\mathrm{H}^{+}(\mathrm{aq}) \rightleftharpoons \mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})
$$

If a base is added to the buffer system, the $\mathrm{OH}^{-}$ions will be neutralized by the acid in the buffer:

$$
\mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})+\mathrm{OH}^{-}(\mathrm{aq}) \rightleftharpoons \mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

Similarly let us consider a buffer solution prepared by adding comparable amounts of ammonia $\left(\mathrm{NH}_{3}\right)$ and its salt ammonium chloride $\left(\mathrm{NH}_{4} \mathrm{Cl}\right)$ to water. The equilibrium concentrations of both the base and the conjugate acid (from $\mathrm{NH}_{4} \mathrm{Cl}$ ) are assumed to be the same as the starting concentrations as the presence of a common ion suppresses the dissociation of a weak base $\mathrm{NH}_{3}$. A solution containing these two substances has the ability to neutralize either added acid or added base. In the solution $\mathrm{NH}_{4} \mathrm{Cl}$, a strong electrolyte, dissociates completely in water:

$$
\mathrm{NH}_{4} \mathrm{Cl}(\mathrm{aq}) \rightarrow \mathrm{NH}_{4}^{+}(\mathrm{aq})+\mathrm{Cl}^{-}(\mathrm{aq})
$$

## G.C.E. (A/L) CHEMISTRY: UNIT 12 Chemical Equilibrium

If an acid is added, the $\mathrm{H}^{+}$ions will be consumed by the base in the buffer, $\mathrm{NH}_{3}$, according to the equation:

$$
\mathrm{NH}_{3}(\mathrm{aq})+\mathrm{H}^{+}(\mathrm{aq}) \rightleftharpoons \mathrm{NH}_{4}^{+}(\mathrm{aq})
$$

If a base is added, the $\mathrm{OH}^{-}$ions will be consumed by the conjugate acid in the buffer, $\mathrm{NH}_{4}{ }^{+}$, according to the equation:

$$
\mathrm{NH}_{4}{ }^{+}(\mathrm{aq})+\mathrm{OH}^{-}(\mathrm{aq}) \rightleftharpoons \mathrm{NH}_{3}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{aq})
$$

## Common expression for the pH of buffer solutions

A general buffer equation can be derived by considering the following reactions for a weak acid, HA, and the salt of its conjugate weak base, NaA in an aqueous solution. Following reactions are the reactions involved with the species present in a solution.

$$
\begin{gathered}
\mathrm{NaA}(\mathrm{aq}) \rightarrow \mathrm{Na}^{+}(\mathrm{aq})+\mathrm{A}^{-}(\mathrm{aq}) \\
\mathrm{HA}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})+\mathrm{A}^{-}(\mathrm{aq}) \\
2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})+\mathrm{OH}^{-}(\mathrm{aq})
\end{gathered}
$$

Here we can take $\left[\mathrm{A}^{-}(\mathrm{aq})\right]$ as the concentration of $\mathrm{A}^{-}(\mathrm{aq})$ from NaA and assume that the dissociation of HA is suppressed due to the presence of $\mathrm{A}^{-}(\mathrm{aq})$ as the common ion. Substituting these terms in the $K_{\mathrm{a}}$ expression of a weak acid we have,

$$
K_{\mathrm{a}}=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]\left[\mathrm{A}^{-}(\mathrm{aq})\right]}{[\mathrm{HA}(\mathrm{aq})]}
$$

We can also neglect the concentrations of $\mathrm{H}_{3} \mathrm{O}^{+}$and $\mathrm{OH}^{-}$from water as these values are much smaller compared to the initial concentrations of HA and NaA. Hence,

$$
\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]=K_{\mathrm{a}} \frac{[\mathrm{HA}(\mathrm{aq})]}{\left[\mathrm{A}^{-}(\mathrm{aq})\right]}
$$

and finally we get the equation,

$$
\begin{gathered}
\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}+\log \frac{\left[\mathrm{A}^{-}(\mathrm{aq})\right]}{[\mathrm{HA}(\mathrm{aq})]} \\
\text { or } \\
\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}+\log \frac{[\text { conjugate base }]}{[\text { acid }]} .
\end{gathered}
$$

i.e. the Henderson-Hasselbalch equation.

This Henderson-Hasselbalch equation provides a simple way to calculate the pH of a buffer and to determine the change in pH upon adding a strong acid or strong base.

## Example 2.22

How many moles of $\mathrm{NH}_{4} \mathrm{Cl}$ are necessary to be added to $1.0 \mathrm{dm}^{3}$ of $0.10 \mathrm{~mol} \mathrm{dm}^{-3}$ $\mathrm{NH}_{3}$ solution to prepare a buffer solution with $\mathrm{pH} 9.0 . K_{\mathrm{b}}\left(\mathrm{NH}_{3}\right)=1.8 \times 10^{-5}$.

## Answer

$\mathrm{NH}_{3}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{aq}) \rightleftharpoons \mathrm{NH}_{4}^{+}(\mathrm{aq})+\mathrm{OH}^{-}(\mathrm{aq})$
First, we need to estimate the $\left[\mathrm{NH}_{4}{ }^{+}(\mathrm{aq})\right]$

$$
K_{\mathrm{b}}=\frac{\left[\mathrm{NH}_{4}^{+}(\mathrm{aq})\right]\left[\mathrm{OH}^{-}(\mathrm{aq})\right]}{\left[\mathrm{NH}_{3}(\mathrm{aq})\right]}=1.8 \times 10^{-5}
$$

As we know the pH of the solution, $\left[\mathrm{OH}^{-}(\mathrm{aq})\right]$ can be calculated.

$$
\begin{aligned}
& \mathrm{pOH}=14-\mathrm{pH}=5.0 \text { and hence }\left[\mathrm{OH}^{-}(\mathrm{aq})\right]=1.0 \times 10^{-5} \mathrm{~mol} \mathrm{dm}^{-3} \\
& \begin{aligned}
{\left[\mathrm{NH}_{4}^{+}(\mathrm{aq})\right] } & =K_{\mathrm{b}} \frac{\left[\mathrm{NH}_{3}(\mathrm{aq})\right]}{\left[\mathrm{OH}^{-}(\mathrm{aq})\right]} \\
& =1.8 \times 10^{-5} \mathrm{~mol} \mathrm{dm}^{-3} \times \frac{0.10 \mathrm{~mol} \mathrm{dm}^{-3}}{1.0 \times 10^{-5} \mathrm{~mol} \mathrm{dm}^{-3}} \\
& =0.18 \mathrm{~mol} \mathrm{dm}^{-3}
\end{aligned}
\end{aligned}
$$

$\therefore$ Number of moles of $\mathrm{NH}_{4}{ }^{+}=0.18 \mathrm{~mol} \mathrm{dm}^{-3} \times 1.0 \mathrm{dm}^{3}$

$$
=0.18 \mathrm{~mol}
$$

## Example 2.23

Calculate the pH of a buffer system containing $1.0 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{CH}_{3} \mathrm{COOH}$ and $2.0 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{CH}_{3} \mathrm{COONa}$. What is the pH of the buffer system after the addition of 0.10 mole of HCl to $1.0 \mathrm{dm}^{3}$ of the solution? Assume that the volume of the solution does not change when the HCl is added.
$K_{\mathrm{a}}\left(\mathrm{CH}_{3} \mathrm{COOH}\right)=1.8 \times 10^{-5} \mathrm{~mol} \mathrm{dm}^{-3}$

## Answer

Due to the presence of common ion of $\mathrm{CH}_{3} \mathrm{COO}^{-}$from $\mathrm{CH}_{3} \mathrm{COONa}(\mathrm{aq})$, we can neglect the ionization of $\mathrm{CH}_{3} \mathrm{COOH}$ and hydrolysis of the $\mathrm{CH}_{3} \mathrm{COO}^{-}$ion. Therefore,
$\left[\mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})\right]=1.0 \mathrm{~mol} \mathrm{dm}^{-3}$ and $\left[\mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})\right]=2.0 \mathrm{~mol} \mathrm{dm}^{-3}$

$$
\begin{gathered}
K_{\mathrm{a}}=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]\left[\mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})\right]}{\left[\mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})\right]}=1.8 \times 10^{-5} \\
{\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]=\frac{[1.0]}{[2.0]} \times 1.8 \times 10^{-5}} \\
{\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]=9.0 \times 10^{-6}} \\
\mathrm{pH}=5.05
\end{gathered}
$$

After the addition of 0.2 mol of HCl to $1.0 \mathrm{dm}^{3}$ of the buffer solution (i.e. $\left[\mathrm{H}^{+}(\mathrm{aq})\right]=0.10 \mathrm{~mol} \mathrm{dm}^{-3}$ ), complete ionization of HCl acid occurs:

$$
\begin{array}{llll}
\mathrm{HCl}(\mathrm{aq}) & \rightarrow & \mathrm{H}^{+}(\mathrm{aq}) & +\mathrm{Cl}^{-}(\mathrm{aq}) \\
0.10 & 0.10 & 0.10
\end{array} \quad \mathrm{~mol} \mathrm{dm}^{-3}
$$

Then the $\mathrm{H}^{+}$from HCl is neutralized by the $2.0 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{CH}_{3} \mathrm{COONa}$ as

$$
\begin{array}{lccc}
\mathrm{H}^{+}(\mathrm{aq})+\mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq}) & \rightleftharpoons & \mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq}) \\
0.10 & 0.10 & 0.10 \quad \mathrm{~mol} \mathrm{dm}^{-3}
\end{array}
$$

(Equilibrium constant for the reaction is very large and therefore we can assume that the reaction goes to completion giving $0.10 \mathrm{~mol} \mathrm{dm}^{-3}$ of $\mathrm{CH}_{3} \mathrm{COOH}$ )
$\therefore$ The number of moles of acetic acid and the number of moles of acetate ions present in $1.0 \mathrm{dm}^{3}$ solution are,
$\mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})=1.10 \mathrm{~mol}$ or $\left[\mathrm{CH}_{3} \mathrm{COOH}(\mathrm{aq})\right]=1.10 \mathrm{moldm}^{-3}$
$\mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})=1.90 \mathrm{~mol}$ or $\left[\mathrm{CH}_{3} \mathrm{COO}^{-}(\mathrm{aq})\right]=1.90 \mathrm{moldm}^{-3}$
Substituting these values in $\boldsymbol{K}_{\mathrm{a}}$ expression,

$$
\begin{gathered}
{\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]=\frac{1.1}{1.9} \times 1.8 \times 10^{-5}} \\
{\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]=1.04 \times 10^{-5} \mathrm{~mol} \mathrm{dm}^{-3}} \\
\mathrm{pH}=4.98
\end{gathered}
$$

Note: if the initial concentrations of the acid and the salt in the buffer solution are the same, for example, $1.0 \mathrm{~mol} \mathrm{dm}{ }^{-3}$, without adding any acid or base, we get

$$
\begin{aligned}
{\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right] } & =\frac{1.0}{1.0} \times 1.8 \times 10^{-5} \\
{\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right] } & =1.8 \times 10^{-5} \\
\mathrm{pH} & =4.74
\end{aligned}
$$

i.e. $\mathrm{pH}=\mathrm{pK}_{\mathrm{a}}$

This can be easily understood by, applying the equation,

$$
\begin{gathered}
\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}+\log \frac{\left[\mathrm{A}^{-}(\mathrm{aq})\right]}{[\mathrm{HA}(\mathrm{aq})]} \\
\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}+\log \frac{1.0}{1.0} \\
\therefore \mathrm{pH}=\mathrm{p} K_{\mathrm{a}}
\end{gathered}
$$

## Example 2.24

Calculate the pH of a buffer that is $0.020 \mathrm{~mol} \mathrm{dm}^{-3}$ in $\mathrm{NH}_{3}$ and $0.030 \mathrm{~mol} \mathrm{dm}^{-3}$ in $\mathrm{NH}_{4} \mathrm{Cl}$. What is the $p \mathrm{H}$ after adding $1.00 \mathrm{~cm}^{3}$ of $0.10 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{NaOH}$ to $0.10 \mathrm{dm}^{3}$ of this buffer? The acid dissociation constant for $\mathrm{NH}_{4}{ }^{+}$is $5.70 \times 10^{-10} \mathrm{~mol} \mathrm{dm}^{-3}$

## Answer

We can directly use,

$$
\begin{gathered}
\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}+\log \frac{\left[\mathrm{NH}_{3}(\mathrm{aq})\right]}{\left[\mathrm{NH}_{4}^{+}(\mathrm{aq})\right]} \\
\mathrm{pH}=9.24+\log \frac{(0.02)}{(0.03)} \\
\mathrm{pH}=9.06
\end{gathered}
$$

Adding NaOH converts a portion of the $\mathrm{NH}_{4}{ }^{+}$to $\mathrm{NH}_{3}$ due to the following reaction

$$
\mathrm{NH}_{4}^{+}(\mathrm{aq})+\mathrm{OH}^{-}(\mathrm{aq}) \rightleftharpoons \mathrm{NH}_{3}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

Since the equilibrium constant for this reaction is large, we may treat the reaction as if it went to completion. The new concentrations of $\mathrm{NH}_{4}{ }^{+}$and $\mathrm{NH}_{3}$ are therefore
$\left[\mathrm{NH}_{4}^{+}(\mathrm{aq})\right]=\frac{\text { moles of initial } \mathrm{NH}_{4}^{+}-\text {moles of } \mathrm{OH}^{-} \text {added }}{\text { total volume }}$
$\left[\mathrm{NH}_{4}+(\mathrm{aq})\right]=\frac{(0.03) \times(0.1)-(0.1) \times\left(1.0 \times 10^{-3}\right)}{(0.101)}=0.029 \mathrm{~mol} \mathrm{dm}^{-3}$ and
$\left[\mathrm{NH}_{3}(\mathrm{aq})\right]=\frac{\text { moles of initial } \mathrm{NH}_{3}+\text { moles of } \mathrm{OH}^{-} \text {added }}{\text { total volume }}$
$\left[\mathrm{NH}_{3}(\mathrm{aq})\right]=\frac{(0.02) \times(0.1)+(0.1) \times\left(1.0 \times 10^{-3}\right)}{(0.101)}=0.021 \mathrm{~mol} \mathrm{dm}^{-3}$
Substituting these in the equation, we get

$$
\begin{gathered}
\mathrm{pH}=\mathrm{p} K_{\mathrm{a}}+\log \frac{\left[\mathrm{NH}_{3}(\mathrm{aq})\right]}{\left[\mathrm{NH}_{4}^{+}(\mathrm{aq})\right]} \\
\mathrm{pH}= \\
\mathrm{pH}=9.24+\log \frac{(0.021)}{(0.029)} \\
\end{gathered}
$$

From the above examples we can see that the addition of a little amount of acid or base does not afftect the pH of the buffer solutions significantly. This nature is explained in Figure 2.26 in which the addition of either an acid or a base to the buffer solutions are compared with the addition of an acid or a base to water and buffer solutions with different concentrations of acid-base pairs. Figure 2.27 also explains the events happening in buffer solutions when an acid or a base is added. Finally, the following can be considered the basic charateristics of buffer solutions.
(i) Contain relatively large concentrations of a weak acid (base) and its conjugate base (acid).
(ii) When acid is added, it reacts with the conjugate base.
(iii) When base is added, it reacts with the conjugate acid.
(iv) pH is determined by the ratio of the base and acid.

These characteristics are depicted in Figure 2.26 and Figure 2.27.

Figure 2.26 Comparison of buffer action for acidic- and basic- buffers is given in (a) and (b) sides respectively. When the strength of the acid and salt (conjugate base) of the buffer is high the variation in pH with the addition of either an acid or a base is minimal. The varaiation in pH upon the addition of either an acid or a base to water and acid alone (or base alone) are also shown for comparison.

$$
\begin{gathered}
\text { When } H(a q) \text { is added } \\
\text { Added } H(a q) \text { are } \\
\text { replaced by A (aq) and } \\
{[A(\text { aq })] /[H A(a q)] \text { remains }} \\
\text { more or less the same } \\
H+A \rightleftharpoons H A
\end{gathered}
$$

Figure 2.27 Summary of buffer action

For convenience, we will assume that an acid-base buffer exists when the concentration ratio of weak base to weak acid is between 0.1 and 10. Applying the HendersonHasselbalch equation:

$$
\begin{aligned}
& \mathrm{pH}=\mathrm{p} K_{\mathrm{a}}+\log \frac{1}{10}=\mathrm{p} K_{\mathrm{a}}-1 \\
& \text { and } \\
& \mathrm{pH}=\mathrm{p} K_{\mathrm{a}}+\log \frac{10}{1}=\mathrm{p} K_{\mathrm{a}}+1
\end{aligned}
$$

Thus it is seen that acid-base buffer exists within the range of $\mathbf{p H}=\mathbf{p} K_{\mathrm{a}} \pm \mathbf{1}$

### 2.4 Solubility equilibria

Solubility of ionic solids in water varies a great deal. Some of these (like calcium chloride, sodium chloride) are so soluble that they are hygroscopic in nature and even absorb water vapour from the atmosphere. Others (such as lithium fluoride) have so little solubility that they are commonly termed insoluble. The solubility depends on a number of factors important amongst which are the lattice enthalpy of the salt and the solvation enthalpy of the ions in a solution. For a salt to dissolve in a solvent, the strong forces of attraction between its ions (lattice enthalpy) must be overcome by the ion-solvent interactions. The solvation enthalpy of ions is referred to in terms of solvation which is always negative i.e. energy is released in the process of solvation. The amount of solvation enthalpy depends on the nature of the solvent. In case of a non-polar (covalent) solvent, solvation enthalpy is small and hence, not sufficient to overcome lattice enthalpy of the salt. Consequently, the salt does not dissolve in non-polar solvent. As a general rule, for a salt to be able to dissolve in a particular solvent, its solvation enthalpy must be greater than its lattice enthalpy so that the latter may be overcome by the former. With this fact we can start to understand the term solubility in the following way: First see the solubility of ionic salts and then understand the solubility of molecular compounds/ covalent compounds and then see the difference with sparingly soluble salts in a saturated solution.

### 2.4.1 Ionic and covalent solutions

Solutions are made up of two components, the solute and the solvent. There are many examples for different types of solutions such as solid-solid (metal alloys), solid-liquid (salt-water), liquid-liquid (alcohol-water), liquid-gas (soft drinks like soda water) and gas- gas (air) in which we see that he two components are distributed homogeneously to making the system appear to be in one phase. In this section we mainly deal with the solid-liquid systems where the solvent is water or in other words we deal with "ionic equilibria".

We know that an ionic or covalent solution is a homogeneous mixture consisting of one phase when the concentration of the solute is small or the solution is very dilute. In an ionic solution like the salt solution, NaCl is dissolved (or dissociated) in water to produce ions of $\mathrm{Na}^{+}$(aq) and $\mathrm{Cl}^{-}(\mathrm{aq})$ while in a covalent solution, a covalent substance like sugar is
dissolved in water. That is, ionic compounds dissolve by separating into respective ions and covalent substances dissolve as the entire molecule. Therefore, we can simply distinguish these two compounds by the following equations.

$$
\begin{aligned}
& \text { Ionic compounds: } \mathrm{NaCl}(\mathrm{~s}) \rightarrow \mathrm{Na}^{+}(\mathrm{aq})+\mathrm{Cl}^{-}(\mathrm{aq}) \\
& \text { Covalent compounds: } \mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}(\mathrm{~s}) \rightarrow: \mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}(\mathrm{aq})
\end{aligned}
$$

This in turn helps us to understand that ionic solutions as electrolytes which show conductivity while covalent or molecular solutions are non-electrolytes which do not show conductivity.

When we consider ionic salts, each salt has its characteristic solubility which depends on the temperature. It is possible to classify salts on the basis of their solubility in the following three categories.

$$
\begin{array}{ll}
\text { Category I : } & \text { Soluble }- \text { Solubility }>0.10 \mathrm{~mol} \mathrm{dm}^{-3} \\
\text { Category II : } & \text { Slightly soluble }-0.01 \mathrm{~mol}^{-3}<\text { Solubility }<0.10 \mathrm{~mol} \mathrm{dm}^{-3} \\
\text { Category III : } & \text { Sparingly soluble }- \text { Solubility }<0.01 \mathrm{~mol} \mathrm{dm}^{-3}
\end{array}
$$

Usually we know that when 0.10 mol of solid NaCl is dissolved in $1.00 \mathrm{dm}^{3}$ of water, i.e. the concentration of solution is $0.10 \mathrm{~mol} \mathrm{dm}^{-3}$, it produces $0.10 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{Na}^{+}(\mathrm{aq})$ and $0.10 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{Cl}^{-}(\mathrm{aq})$ ions showing complete dissociation.

$$
\begin{array}{ccc}
\mathrm{NaCl}(\mathrm{~s})+\text { Water } \rightarrow \underset{\mathrm{NaCl}(\mathrm{aq})}{\mathrm{Na})} \rightarrow & \mathrm{Na}^{+}(\mathrm{aq})+\mathrm{Cl}^{-}(\mathrm{aq}) \\
0.10 & 0.10 & 0.10
\end{array} \mathrm{~mol} \mathrm{dm}^{-3}
$$

A set of conditions need to be considered to understand the solubility. First, a saturated solution is needed in which the maximum amount of solute is dissolved and in the case of sparingly soluble salts some amount of the solid has to remain still.

Under this condition, we can understand that there is a heterogeneous equilibrium in the system as the rate of dissolution equals the rate of precipitation or crystallization - or in other words the system is in dynamic equilibrium. Simply, the following equation explains this situation.

$$
\operatorname{MX}(\mathrm{s}) \rightleftharpoons \mathrm{M}^{+}(\mathrm{aq})+\mathrm{X}^{-}(\mathrm{aq})
$$

## G.C.E. (A/L) CHEMISTRY: UNIT 12 Chemical Equilibrium

Figure 2.28 In saturated solutions dynamic equilibrium exists between undissolved solids and ionic species in the solution. Hence solid continues to dissolve and ion-pairs continue to form the solid and the rate of dissolution is equal to the rate of precipitation.

Solubility of a substance: Equilibrium concentration of a substance in a saturated solution at a given temperature or solubility is a measure of how much of a solute (maximum amount)can dissolve in a solvent at a given temperature. Therefore it is a quantitative value and is expressed mainly as molar solubility $\left(\mathrm{mol} \mathrm{dm}^{-3}\right)$. Other units used to express solubility are $\mathrm{g} \mathrm{dm}^{-3}, \mathrm{~g} \mathrm{~cm}^{-3}$ etc. i.e to find solubility experimentally, it is necessary to find the amount (mass) of solute required to make a known volume of a saturated solution.

Note: There are two ways by which a saturated aqueous solution of a salt MX can be made.
(i) Direct method: Add solid MX salt to water with vigorous stirring until excess MX salt remains on the bottom of the beaker.
(ii) Indirect method: Mix two solutions together, one containing $M^{+}$and the other containing $X^{*}$ and at a certain point a saturated solution of $M X$ will be formed.

## G.C.E. (A/L) CHEMISTRY: UNIT 12 Chemical Equilibrium

## Example 2.25

$1.00 \mathrm{dm}^{3}$ of a saturated AgCl solution was prepared by dissolving $1.8 \times 10^{-3} \mathrm{~g}$ of AgCl completely. What is the molar solubility of AgCl ? $\left(\mathrm{AgCl}: 143.4 \mathrm{~g} \mathrm{~mol}^{-1}\right)$

## Answer

Amount of moles of $\mathrm{AgCl}=1.8 \times 10^{-3} \mathrm{~g} / 143.4 \mathrm{~g} \mathrm{~mol}^{-1}=1.26 \times 10^{-5} \mathrm{~mol}$ Since molar solubility is expressed in units of $\mathrm{mol} \mathrm{dm}^{-3}$ :
Molar solubility $=1.26 \times 10^{-5} \mathrm{~mol} / 1.00 \mathrm{dm}^{3}=1.26 \times 10^{-5} \mathrm{~mol} \mathrm{dm}^{-3}$
We can express solubility in other units as $1.8 \times 10^{-3} \mathrm{~g} \mathrm{dm}^{-3}$

### 2.4.2 Solubility product (solubility product constant)

Let us now consider a solid MX in contact with its saturated aqueous solution. The equilibrium between the undissolved solid and the ions in a saturated solution is represented by the equation:

$$
\mathrm{MX}(\mathrm{~s}) \rightleftharpoons \mathrm{M}^{+}(\mathrm{aq})+\mathrm{X}^{-}(\mathrm{aq})
$$

The equilibrium constant $K$ is given by the equation:

$$
K=\frac{\left[\mathrm{M}^{+}(\mathrm{aq})\right]\left[\mathrm{X}^{-}(\mathrm{aq})\right]}{[\mathrm{MX}(\mathrm{~s})]}
$$

For a pure solid substance the concentration remains constant and we can write;

$$
\begin{gathered}
K[\mathrm{MX}(\mathrm{~s})]=\left[\mathrm{M}^{+}(\mathrm{aq})\right]\left[\mathrm{X}^{-}(\mathrm{aq})\right] \\
\therefore K_{\mathrm{sp}}=\left[\mathrm{M}^{+}(\mathrm{aq})\right]\left[\mathrm{X}^{-}(\mathrm{aq})\right]
\end{gathered}
$$

In general, if we have an equilibrium;

$$
\mathrm{M}_{\mathrm{m}} \mathrm{X}_{\mathrm{n}}(\mathrm{~s}) \rightleftharpoons \mathrm{mM}^{\mathrm{nt}}(\mathrm{aq})+\mathrm{nX}^{\mathrm{m}-}(\mathrm{aq})
$$

Solubility product,

$$
K_{\mathrm{sp}}=\left[\mathrm{M}^{\mathrm{n}+}(\mathrm{aq})\right]^{\mathrm{m}}\left[\mathrm{X}^{\mathrm{m}-}(\mathrm{aq})\right]^{\mathrm{n}}
$$

$K_{\text {sp }}$ is called as the solubility product constant or simply the solubility product and its expression does not have a denominator because the reactant is a solid. It has to be noted that the solubility product is defined only for saturated solutions. Large values for $K_{\mathrm{sp}}$ indicate that the products are favored; therefore, the larger the value of $K_{s p}$, the greater the number of ions and hence the greater the solubility of the compound. Usually, it has no units as we described in equilibrium constant when the concentrations are measured with respect to standard concentration of $1.0 \mathrm{~mol} \mathrm{dm}^{-3}$. Unless a mention is made about the standard conditions, we include the respective units for the concentrations appearing in

## G.C.E. (A/L) CHEMISTRY : UNIT 12 Chemical Equilibrium

the solubility product expression. The units for solubility products differ depending on the solubility product expression.

In general, if we have an equilibrium;

$$
\mathrm{M}_{\mathrm{m}} \mathrm{X}_{\mathrm{n}}(\mathrm{~s}) \rightleftharpoons \mathrm{mM}^{\mathrm{n}+}(\mathrm{aq})+\mathrm{nX}^{\mathrm{m}-}(\mathrm{aq})
$$

Solubility product,

$$
K_{\mathrm{sp}}=\left[\mathrm{M}^{\mathrm{n}+}(\mathrm{aq})\right]^{\mathrm{m}}\left[\mathrm{X}^{\mathrm{m}-}(\mathrm{aq})\right]^{\mathrm{n}}
$$

Units:

$$
\begin{gathered}
\left(\mathrm{mol}^{\mathrm{m}} \mathrm{dm}^{-3 \mathrm{~m}}\right)\left(\mathrm{mol}^{\mathrm{n}} \mathrm{dm}^{-3 \mathrm{n}}\right) \\
\mathbf{m o l}^{(\mathbf{m}+\mathbf{n})} \mathbf{d m}^{-3(\mathbf{m}+\mathbf{n})}
\end{gathered}
$$

Simply for the equilibrium: $\mathrm{MX}(\mathrm{s}) \rightleftharpoons \mathrm{M}^{+}(\mathrm{aq})+\mathrm{X}^{-}(\mathrm{aq})$

$$
K_{\mathrm{sp}}=\left[\mathrm{M}^{+}(\mathrm{aq})\right]\left[\mathrm{X}^{-}(\mathrm{aq})\right] \mathrm{mol}^{2} \mathrm{dm}^{-6}
$$

### 2.4.3 Solubility and solubility product calculations

Calculations involving $K_{\text {sp }}$ are simpler than for previous equilibrium calculations because the reactant is a solid and therefore omitted from the equilibrium expression. There are only two types of problems that need to be solved:
(a) Calculating $K_{\text {sp }}$ from solubility data or
(b) Calculating solubility from $K_{\text {sp }}$.

Consider the example,

$$
\begin{gathered}
\mathrm{AgCl}(\mathrm{~s}) \rightleftharpoons \mathrm{Ag}^{+}(\mathrm{aq})+\mathrm{Cl}^{-}(\mathrm{aq}): K_{\mathrm{sp}}=\left[\mathrm{Ag}^{+}(\mathrm{aq})\right]\left[\mathrm{Cl}^{-}(\mathrm{aq})\right] \\
\mathrm{At} 298 \mathrm{~K}, \quad K_{\mathrm{sp}}=1.60 \times 10^{-10} \mathrm{~mol}^{2} \mathrm{dm}^{-6}
\end{gathered}
$$

When we consider the above equilibrium, concentrations of the two ions will be equal to the molar solubility of silver chloride. If molar solubility is $s$, then

$$
\mathrm{AgCl}(\mathrm{~s}) \rightleftharpoons \underset{s}{ } \mathrm{Ag}^{+}(\mathrm{aq})+\mathrm{Cl}^{-}(\mathrm{aq})
$$

At the equilibrium:

$$
\text { At } 298 \mathrm{~K}, \quad K_{\mathrm{sp}}=1.60 \times 10^{-10} \mathrm{~mol}^{2} \mathrm{dm}^{-6}=\boldsymbol{s} \times \boldsymbol{s}=\boldsymbol{s}^{2}
$$

Thus, at 298 K , molar solubility of silver chloride will be equal to $1.26 \times$ $10^{-5} \mathrm{~mol} \mathrm{dm}^{-3}$.

A solid salt of the general formula

$$
\mathrm{M}_{\mathrm{m}} \mathrm{X}_{\mathrm{n}}(\mathrm{~s}) \rightleftharpoons \mathrm{mM}^{\mathrm{nt}}(\mathrm{aq})+\mathrm{nX}^{\mathrm{m}-}(\mathrm{aq})
$$

Molar solubility $S$ in equilibrium $m s \quad n s$

$$
K_{\mathrm{sp}}=\left[\mathrm{M}^{\mathrm{n}+}(\mathrm{aq})\right]^{\mathrm{m}}\left[\mathrm{X}^{\mathrm{m}-(\mathrm{aq})}\right]^{\mathrm{n}}
$$

$$
\begin{aligned}
& K_{s p}=(\mathrm{m} \mathrm{~s})^{\mathrm{m}}(\mathrm{n} \mathrm{~s})^{\mathrm{n}}=\mathrm{m}^{\mathrm{m}} \mathrm{n}^{\mathrm{n}} \mathrm{~s}^{(\mathrm{m}+\mathrm{n})} \\
& S^{(\mathrm{m}+\mathrm{n})}=\frac{K_{\mathrm{sp}}}{\mathrm{~m}^{\mathrm{m}} \mathrm{n}^{\mathrm{n}}} \\
& S=\left[\frac{K_{\mathrm{sp}}}{\mathrm{~m}^{\mathrm{m}} \mathrm{n}^{\mathrm{n}}}\right]^{1 /(\mathrm{m}+\mathrm{n})}
\end{aligned}
$$

## Example 2.26

Derive an expression for the solubility $(s)$ of aqueous saturated solution $\mathrm{Zr}_{3}\left(\mathrm{PO}_{4}\right)_{4}(\mathrm{~s})$ at 298 K .

## Answer

$$
\mathrm{Zr}_{3}\left(\mathrm{PO}_{4}\right)_{4}(\mathrm{~s}) \rightleftharpoons \underset{3 s}{3 \mathrm{Zr}^{4+}(\mathrm{aq})+} \underset{4 s}{4 \mathrm{PO}_{4}{ }^{3-}(\mathrm{aq})}
$$

At equilibrium:

$$
\begin{array}{r}
K_{\mathrm{sp}}=\left[\mathrm{Zr}^{4+}(\mathrm{aq})\right]^{3}\left[\mathrm{PO}_{4}^{3-}(\mathrm{aq})\right]^{4}=(3 s)^{3}(4 s)^{4}=6912(s)^{7} \\
\therefore s=\left[\frac{K_{\mathrm{sp}}}{6912}\right]^{1 / 7}
\end{array}
$$

In this example we can notice that $K_{\mathrm{sp}}=\left[\mathrm{Zr}^{4+}(\mathrm{aq})\right]^{3}\left[\mathrm{PO}_{4}{ }^{3-}(\mathrm{aq})\right]^{4}$ has units $\left(\text { moldm }{ }^{-3}\right)^{7}$. And the units of $s$ is $\left[\left(\mathrm{mol} \mathrm{dm}^{-3}\right)^{7}\right]^{\frac{1}{7}}=\mathrm{mol} \mathrm{dm}{ }^{-3}$

That is the units of molar solubility.

## Example 2.27

At $298 \mathrm{~K}, 100.00 \mathrm{~cm}^{3}$ of a saturated $\mathrm{PbI}_{2}$ solution was prepared by dissolving $5.60 \times 10^{-2} \mathrm{~g} \mathrm{PbI}_{2}(\mathrm{~s})$. Calculate $K_{\mathrm{sp}}$.

## Answer

First we need the molar solubility of $\mathrm{PbI}_{2}$ :

$$
\begin{aligned}
& \text { Moles of } \mathrm{PbI}_{2}=5.60 \times 10^{-2} \mathrm{~g} / 461 \mathrm{~g} \mathrm{~mol}^{-1}=1.21 \times 10^{-4} \mathrm{~mol} \\
& \begin{aligned}
\text { Molar solubility of } \mathrm{PbI}_{2} & =1.21 \times 10^{-4} \mathrm{~mol} / 0.100 \mathrm{dm}^{3} \\
& =1.21 \times 10^{-3} \mathrm{~mol} \mathrm{dm}
\end{aligned}
\end{aligned}
$$

Next calculate the concentration of the ions and substitute in the $K s p$ expression:

$$
\mathrm{PbI}_{2}(\mathrm{~s}) \rightleftharpoons \mathrm{Pb}^{2+}(\mathrm{aq})+2 \mathrm{I}^{-}(\mathrm{aq})
$$

At equilibrium : $\quad\left[\mathrm{Pb}^{2+}(\mathrm{aq})\right]=1.21 \times 10^{-3} \mathrm{~mol} \mathrm{dm}^{-3}$ and

$$
\left[\mathrm{I}^{-}(\mathrm{aq})\right]=2 \times 1.21 \times 10^{-3} \mathrm{~mol} \mathrm{dm}^{-3}=2.42 \times 10^{-3} \mathrm{~mol} \mathrm{dm}^{-3}
$$

$K_{\mathrm{sp}}=\left[\mathrm{Pb}^{2+}(\mathrm{aq})\right]\left[\mathrm{I}^{-}(\mathrm{aq})\right]^{2}$
$K_{\text {sp }}=\left(1.21 \times 10^{-3} \mathrm{~mol} \mathrm{dm}^{-3}\right) \times\left(2.42 \times 10^{-3} \mathrm{~mol} \mathrm{dm}^{-3}\right)^{2}$
$K_{\mathrm{sp}}=7.1 \times 10^{-9} \mathrm{~mol}^{3} \mathrm{dm}^{-9}$

## Example 2.28

At 298 K , the values of $K_{\mathrm{sp}}$ of two sparingly soluble compounds $\mathrm{Ni}(\mathrm{OH})_{2}$ and AgCN are $2.0 \times 10^{-15} \mathrm{~mol}^{3} \mathrm{dm}^{-9}$ and $6 \times 10^{-17} \mathrm{~mol}^{2} \mathrm{dm}^{-6}$ respectively. Which salt is more soluble?

## Answer

Consider the equilibrium,

$$
\mathrm{Ni}(\mathrm{OH})_{2}(\mathrm{~s}) \rightleftharpoons \mathrm{Ni}^{2+}(\mathrm{aq})+2 \mathrm{OH}^{-}(\mathrm{aq})
$$

If the solubility is $x$,
At equilibrium :
$x \quad 2 x$
$K_{\text {sp }}=\left[\mathrm{Ni}^{2+}(\mathrm{aq})\right]\left[\mathrm{OH}^{-}(\mathrm{aq})\right]^{2}=4 x^{3}$
$4 x^{3}=2.0 \times 10^{-15} \mathrm{~mol}^{3} \mathrm{dm}^{-9}$
$x=7.94 \times 10^{-5} \mathrm{~mol} \mathrm{dm}^{-3}$

## Similarly,

$$
\mathrm{AgCN}(\mathrm{~s}) \rightleftharpoons \mathrm{Ag}^{+}(\mathrm{aq})+\mathrm{CN}^{-}(\mathrm{aq})
$$

If the solubility is $y$,
At equilibrium :
$y \quad y$
$K_{\text {sp }}=\left[\mathrm{Ag}^{+}(\mathrm{aq})\right]\left[\mathrm{CN}^{-}(\mathrm{aq})\right]=y^{2}$
$y^{2}=6 \times 10^{-17} \mathrm{~mol}^{2} \mathrm{dm}^{-6}$
$y=7.8 \times 10^{-9} \mathrm{~mol} \mathrm{dm}^{-3}$
we can notice that; $x>y$
Therefore, $\mathrm{Ni}(\mathrm{OH})_{2}(\mathrm{~s})$ is more soluble than $\mathrm{AgCN}(\mathrm{s})$.
(It is also possible to predict this comparing $K_{\text {sp }}$ values; Since $K_{\text {sp }}\left(\mathrm{Ni}(\mathrm{OH})_{2}(\mathrm{~s})\right)>K_{\text {sp }}$ $(\mathrm{AgCN}(\mathrm{s}))$, solubility of $\mathrm{Ni}(\mathrm{OH})_{2}(\mathrm{~s})$ is higher than that of $\left.\mathrm{AgCN}(\mathrm{s})\right)$.

## Calculating ion concentrations from $K_{\text {sp }}$

## Example 2.29

Estimate the $\left[\mathrm{Ag}^{+}(\mathrm{aq})\right]$ in a saturated solution of $\mathrm{Ag}_{2} \mathrm{CO}_{3}$ at 298 K .
$K_{\text {sp }}\left(\mathrm{Ag}_{2} \mathrm{CO}_{3}\right)=8.1 \times 10^{-12} \mathrm{~mol}^{3} \mathrm{dm}^{-9}$

## Answer

First, consider the equilibrium, and if $\boldsymbol{x}$ is the molar solubility, we can write

$$
\mathrm{Ag}_{2} \mathrm{CO}_{3(\mathrm{~s})} \rightleftharpoons 2 \mathrm{Ag}^{+}(\mathrm{aq})+\mathrm{CO}_{3}{ }^{2-}(\mathrm{aq})
$$

At equilibrium: $\quad 2 x \quad x \quad \mathrm{~mol} \mathrm{dm}^{-3}$

$$
K_{\mathrm{sp}}=\left[\mathrm{Ag}^{+}(\mathrm{aq})\right]^{2}\left[\mathrm{CO}_{3}{ }^{2-}(\mathrm{aq})\right]
$$

$=(2 x)^{2}(x)=4 x^{3}$
$\therefore 4 x^{3}=8.1 \times 10^{-12} \mathrm{~mol}^{3} \mathrm{dm}^{-9}$
We get
$x=\left(8.1 \times 10^{-12} \mathrm{~mol}^{3} \mathrm{dm}^{-9}\right)^{1 / 3}$
$x=1.26 \times 10^{-4} \mathrm{~mol} \mathrm{dm}^{-3}$
$\therefore\left[\mathrm{Ag}^{+}(\mathrm{aq})\right]=2 x=2 \times 1.26 \times 10^{-4} \mathrm{~mol} \mathrm{dm}^{-3}=2.53 \times 10^{-4} \mathrm{~mol} \mathrm{dm}^{-3}$

## Example 2.30

Which of the saturated solutions AgCl and $\mathrm{Ag}_{2} \mathrm{CO}_{3}$ will have a higher $\left[\mathrm{Ag}^{+}(\mathrm{aq})\right]$ at 298 K ? $\quad K_{\mathrm{sp}}(\mathrm{AgCl})=1.8 \times 10^{-10} \mathrm{~mol}^{2} \mathrm{dm}^{-6}$ and $K_{\mathrm{sp}}\left(\mathrm{Ag}_{2} \mathrm{CO}_{3}\right)=8.1 \times 10^{-12} \mathrm{~mol}^{3} \mathrm{dm}^{-9}$

## Answer

One can note that this problem is similar to the Example 12.29. However, we were asked to estimate $\left[\mathrm{Ag}^{+}(\mathrm{aq})\right]$. Also one has to note that we cannot compare the values of $K_{\text {sp }}$ as the two constants have different units. Therefore, it is necessary to estimate the $\mathrm{Ag}^{+}(\mathrm{aq})$ concentrations in cases.

AgCl

$$
\mathrm{Ag}_{2} \mathrm{CO}_{3}
$$

From previous examples:
[ $\mathrm{Ag}^{+}{ }^{(\mathrm{aq})}$ ]
$1.34 \times 10^{-5} \mathrm{~mol} \mathrm{dm}^{-3}$
$2.53 \times 10^{-4} \mathrm{~mol} \mathrm{dm}^{-3}$

Now we can see that the saturated $\mathrm{Ag}_{2} \mathrm{CO}_{3}$ solution has higher $\left[\mathrm{Ag}^{+}(\mathrm{aq})\right]$ though the $K_{\text {sp }}\left(\mathrm{Ag}_{2} \mathrm{CO}_{3}\right)<K_{\text {sp }}(\mathrm{AgCl})$.

### 2.4.4 Predicting the formation of a precipitate

Whenever two solutions containing ions are mixed, there is a possibility that a precipitate may form. If the concentrations of the ions is $0.10 \mathrm{~mol} \mathrm{dm}^{-3}$ or higher any compound having low solubility will precipitate. However, if the concentrations of the ions is less than $0.10 \mathrm{~mol} \mathrm{dm}^{-3}$, a calculation must be performed to predict the formation of the precipitate.

For example, if we mix equal volumes of $0.20 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{AgNO}_{3}$ and NaCl solutions, a precipitate of $\mathrm{AgCl}(\mathrm{s})$ will form with $\mathrm{NO}_{3}{ }^{-}$and $\mathrm{Na}^{+}$ions as spectators. In this case as $\mathrm{AgNO}_{3}$ and NaCl are strong electrolytes there is a precipitate of AgCl formed with $0.10 \mathrm{~mol} \mathrm{dm}^{-3}$ cocentrations.

However, the situation with very dilute solutions (concentrations $<0.10 \mathrm{~mol} \mathrm{dm}^{-3}$ ) is different: When two soluble salt solutions are mixed, a cation from one solution is introduced to an anion from another solution, and vise versa.

One or both of the new ion combinations (cation and anion) could have low solubility. If this is the case, and there are too many of the low solubility ions present (more than what is necessary for a saturated solution), a precipitate will result.
If there is not enough of the low solubility ions present to reach the saturation concentration, a precipitate will not form and the ions will stay dissolved in solution.

In such situations Ion-product (IP) calculation is required to predict the formation of a precipitate.

Ion-product can be calculated for these mixtures to deduce whether a precipitate will form or not when the two solutions are mixed and the following conditions are defined.

If the Ion-product is larger than the actual $K_{s p}$, the concentration of low solubility ions is greater than saturation, so a precipitate will form.
If the Ion-product is smaller than the actual $K_{s p}$, the concentrations of low solubility ions have not yet reached saturation, a precipitate will not form.

We can summarize the above as;
$\boldsymbol{I P}>\boldsymbol{K}_{\text {sp }}$ then precipitate forms
$\boldsymbol{I P}=\boldsymbol{K}_{\text {sp }}$ then solution is saturated, no precipitate
$\boldsymbol{I P}<\boldsymbol{K}_{\text {sp }}$ then solution is not saturated, no precipitate

## Example 2.31

Will a precipitate form if the solutions $50.00 \mathrm{~cm}^{3}$ of $5.0 \times 10^{-3} \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{Mg}\left(\mathrm{NO}_{3}\right)_{2}$ and $50.00 \mathrm{~cm}^{3}$ of $1.0 \times 10^{-2} \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{~K}_{2} \mathrm{CO}_{3}$ are mixed?
$K_{\mathrm{sp}}\left(\mathrm{MgCO}_{3}\right)=3.5 \times 10^{-8} \mathrm{~mol}^{2} \mathrm{dm}^{-6}$

## Answer

First write the reaction between $\mathrm{Mg}\left(\mathrm{NO}_{3}\right)_{2}$ and $\mathrm{K}_{2} \mathrm{CO}_{3}$

$$
\mathrm{Mg}\left(\mathrm{NO}_{3}\right)_{2}(\mathrm{aq})+\mathrm{K}_{2} \mathrm{CO}_{3}(\mathrm{aq}) \rightarrow 2 \mathrm{KNO}_{3}(\mathrm{aq})+\mathrm{MgCO}_{3}(\mathrm{~s})
$$

As two solutions are being mixed, dilution occurs.
Therefore the concentrations of the solutions are different when mixed.
$\left[\mathrm{Mg}\left(\mathrm{NO}_{3}\right)_{2}(\mathrm{aq})\right]=\left(5.0 \times 10^{-3} \mathrm{~mol} \mathrm{dm}{ }^{-3} \times 50 \times 10^{-3} \mathrm{dm}^{3}\right) / 100 \times 10^{-3} \mathrm{dm}^{3}$

$$
=2.5 \times 10^{-3} \mathrm{~mol} \mathrm{dm}^{-3}
$$

$\left[\mathrm{K}_{2} \mathrm{CO}_{3}(\mathrm{aq})\right]=\left(1.0 \times 10^{-2} \mathrm{~mol} \mathrm{dm}{ }^{-3} \times 50 \times 10^{-3} \mathrm{dm}^{3}\right) / 100 \times 10^{-3} \mathrm{dm}^{3}$

$$
=5.0 \times 10^{-3} \mathrm{~mol} \mathrm{dm}^{-3}
$$

As $\mathrm{Mg}\left(\mathrm{NO}_{3}\right)_{2}(\mathrm{aq})$ and $\mathrm{K}_{2} \mathrm{CO}_{3}(\mathrm{aq})$ dissociate completely, we can write:

\[

\]

As the precipitate formed is $\mathrm{MgCO}_{3}$ :

$$
\mathrm{MgCO}_{3}(\mathrm{~s}) \rightleftharpoons \mathrm{Mg}^{2+}(\mathrm{aq})+\mathrm{CO}_{3}{ }^{2-}(\mathrm{aq})
$$

$K_{\mathrm{sp}}=\left[\mathrm{Mg}^{2+}(\mathrm{aq})\right]\left[\mathrm{CO}_{3}{ }^{2-}(\mathrm{aq})\right]$
Ion Product $=\left[\mathrm{Mg}^{2+}(\mathrm{aq})\right]\left[\mathrm{CO}_{3}{ }^{2-}(\mathrm{aq})\right]=\left(2.5 \times 10^{-3}\right)\left(5.0 \times 10^{-3}\right) \mathrm{mol}^{2} \mathrm{dm}^{-6}$

$$
=12.5 \times 10^{-6} \mathrm{~mol}^{2} \mathrm{dm}^{-6}
$$

$I P\left(12.5 \times 10^{-6} \mathrm{~mol}^{2} \mathrm{dm}^{-6}\right)>K_{\mathrm{sp}}\left(\mathrm{MgCO}_{3}\right)\left(3.5 \times 10^{-8} \mathrm{~mol}^{2} \mathrm{dm}^{-6}\right)$
Therefore a precipitate of $\mathrm{MgCO}_{3}$ will form.

## Example 2.32

Will a precipitate form if $50.00 \mathrm{~cm}^{3}$ of $1.0 \times 10^{-3} \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{CaCl}_{2}$ solution is added to $50.00 \mathrm{~cm}^{3}$ of $1.0 \times 10^{-2} \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{Na}_{2} \mathrm{SO}_{4}$ solution? $K_{\mathrm{sp}}\left(\mathrm{CaSO}_{4}\right)=2.4 \times 10^{-5} \mathrm{~mol}^{2} \mathrm{dm}^{-6}$

## Answer

First write the reaction between $\mathrm{Mg}\left(\mathrm{NO}_{3}\right)_{2}$ and $\mathrm{K}_{2} \mathrm{CO}_{3}$.

$$
\mathrm{CaCl}_{2}(\mathrm{aq})+\mathrm{Na}_{2} \mathrm{SO}_{4}(\mathrm{aq}) \rightarrow 2 \mathrm{NaCl}(\mathrm{aq})+\mathrm{CaSO}_{4}(\mathrm{~s})
$$

As two solutions are mixed, dilution occurrs
Therefore the concentrations of the solutions are different when mixed.

$$
\begin{aligned}
{\left[\mathrm{CaCl}_{2}(\mathrm{aq})\right] } & =\left(1.0 \times 10^{-3} \mathrm{~mol} \mathrm{dm}^{-3} \times 50 \times 10^{-3} \mathrm{dm}^{3}\right) / 100 \times 10^{-3} \mathrm{dm}^{3} \\
& =5.0 \times 10^{-4} \mathrm{~mol} \mathrm{dm}^{-3}
\end{aligned}
$$

```
\(\left[\mathrm{Na}_{2} \mathrm{SO}_{4}(\mathrm{aq})\right]=\left(1.0 \times 10^{-2} \mathrm{~mol} \mathrm{dm}^{-3} \times 50 \times 10^{-3} \mathrm{dm}^{3}\right) / 100 \times 10^{-3} \mathrm{dm}^{3}\)
\[
=5.0 \times 10^{-3} \mathrm{~mol} \mathrm{dm}^{-3}
\]
\[
\mathrm{CaCl}_{2}(\mathrm{aq}) \rightarrow \mathrm{Ca}^{2+}(\mathrm{aq})+2 \mathrm{Cl}^{-}(\mathrm{aq})
\]
\[
5.0 \times 10^{-4} \quad 5.0 \times 10^{-4} \quad \mathrm{~mol} \mathrm{dm}^{-3}
\]
\[
\mathrm{Na}_{2} \mathrm{SO}_{4}(\mathrm{aq}) \rightarrow 2 \mathrm{Na}^{+}(\mathrm{aq})+\mathrm{SO}_{4}{ }^{2-}(\mathrm{aq})
\]
\[
5.0 \times 10^{-3} \quad 5.0 \times 10^{-3} \quad \mathrm{~mol} \mathrm{dm}^{-3}
\]
```

As the precipitate formed is $\mathrm{CaSO}_{4}$ :

$$
\mathrm{CaSO}_{4}(\mathrm{~s}) \rightleftharpoons \mathrm{Ca}^{2+}(\mathrm{aq})+\mathrm{SO}_{4}{ }^{2-}(\mathrm{aq})
$$

$K_{\text {sp }}=\left[\mathrm{Ca}^{2+}(\mathrm{aq})\right]\left[\mathrm{SO}_{4}{ }^{2-}(\mathrm{aq})\right]$
Ion Product $=\left[\mathrm{Ca}^{2+}(\mathrm{aq})\right]\left[\mathrm{SO}_{4}{ }^{2-}(\mathrm{aq})\right]=\left(5.0 \times 10^{-4}\right)\left(5.0 \times 10^{-3}\right) \mathrm{mol}^{2} \mathrm{dm}^{-6}$

$$
=2.5 \times 10^{-6} \mathrm{~mol}^{2} \mathrm{dm}^{-6}
$$

$I P\left(2.5 \times 10^{-6} \mathrm{~mol}^{2} \mathrm{dm}^{-6}\right)<K_{\mathrm{sp}}\left(\mathrm{CaSO}_{4}\right)=2.4 \times 10^{-5} \mathrm{~mol}^{2} \mathrm{dm}^{-6}$
Therefore a precipitate of $\mathrm{CaSO}_{4}$ will not be formed.

## Example 2.33

What is the maximum $\left[\mathrm{Sr}^{2+}(\mathrm{aq})\right]$ that can exist in a $0.020 \mathrm{~mol} \mathrm{dm}{ }^{-3}$ solution of $\mathrm{K}_{2} \mathrm{SO}_{4}$ without forming a precipitate of $\mathrm{SrSO}_{4} ? K_{\mathrm{sp}}\left(\mathrm{SrSO}_{4}\right)=3.2 \times 10^{-7} \mathrm{~mol}^{2} \mathrm{dm}^{-6}$

Answer

$$
\begin{aligned}
\mathrm{K}_{2} \mathrm{SO}_{4}(\mathrm{aq}) \rightarrow 2 \mathrm{~K}^{+}(\mathrm{aq})+ & \mathrm{SO}_{4}{ }^{2-}(\mathrm{aq}) \\
2.0 \times 10^{-2} & \\
& 2.0 \times 10^{-2}
\end{aligned} \mathrm{~mol} \mathrm{dm}{ }^{-3}
$$

$\mathrm{SrSO}_{4}(\mathrm{~s}) \rightleftharpoons \mathrm{Sr}^{2+}(\mathrm{aq})+\mathrm{SO}_{4}{ }^{2-}(\mathrm{aq})$
$K_{\mathrm{sp}}=\left[\mathrm{Sr}^{2+}(\mathrm{aq})\right]\left[\mathrm{SO}_{4}{ }^{2-}(\mathrm{aq})\right]$
$\therefore 3.2 \times 10^{-7} \mathrm{~mol}^{2} \mathrm{dm}^{-6}=\left[\mathrm{Sr}^{2+}(\mathrm{aq})\right]\left(2.0 \times 10^{-2} \mathrm{~mol} \mathrm{dm}^{-3}\right)$
$\left[\mathrm{Sr}^{2+}(\mathrm{aq})\right]=1.6 \times 10^{-5} \mathrm{~mol} \mathrm{dm}^{-3}$

## Example 2.34

XA(s) and YA(s) are two sparingly water soluble salts.
At $298 \mathrm{~K}, K_{\mathrm{sp}}(\mathrm{XA})=1.80 \times 10^{-10} \mathrm{~mol}^{2} \mathrm{dm}^{-6}$ and $K_{\text {sp }}(\mathrm{YA})=1.80 \times 10^{-7} \mathrm{~mol}^{2} \mathrm{dm}^{-6}$. A completely water soluble salt of NaA is added slowly to a $1.00 \mathrm{dm}^{3}$ solution containing 0.100 moles of $\mathrm{X}^{+}(\mathrm{aq})$ and $\mathrm{Y}^{+}(\mathrm{aq})$.
(i) Predict which of the salts precipitates first.
(ii) Calculate also the cation concentration that remains in the solution of the salt that precipitates first when the second salt begins to precipitate.

## Answer

(i) For XA
$K_{\mathrm{sp}}=\left[\mathrm{X}^{+}(\mathrm{aq})\right]\left[\mathrm{A}^{-}(\mathrm{aq})\right]$
$\left[\mathrm{A}^{-}(\mathrm{aq})\right]=K_{\mathrm{sp}} /\left[\mathrm{X}^{+}(\mathrm{aq})\right]=\left(1.80 \times 10^{-10} / 0.100\right) \mathrm{mol} \mathrm{dm}^{-3}=1.80 \times 10^{-9} \mathrm{~mol} \mathrm{dm}^{-3}$

## For YA

$K_{\mathrm{sp}}=\left[\mathrm{Y}^{+}(\mathrm{aq})\right][\mathrm{A}(\mathrm{aq})]$
$\left[\mathrm{A}^{-}(\mathrm{aq})\right]=K_{\mathrm{sp}}\left[\mathrm{Y}^{+}(\mathrm{aq})\right]=\left(1.80 \times 10^{-7} / 0.100\right) \mathrm{mol} \mathrm{dm}^{-3}=1.80 \times 10^{-6} \mathrm{~mol} \mathrm{dm}^{-3}$
[ $\left.\mathrm{A}^{-}(\mathrm{aq})\right]$ necessary to precipitate XA is less than that needed to precipitate YA.
$\therefore$ XA precipitates first.
(ii) $K_{\text {sp }(\mathrm{XA})}=\left[\mathrm{X}^{+}(\mathrm{aq})\right]\left[\mathrm{A}^{-}(\mathrm{aq})\right]$
at this stage $\left[\mathrm{A}^{-}(\mathrm{aq})\right]$ is the $\left[\mathrm{A}^{-}(\mathrm{aq})\right]$ needed to start precipitation of YA.
$\left[\mathrm{X}^{+}(\mathrm{aq})\right]$ left in the solution $=\left(1.80 \times 10^{-10} / 1.80 \times 10^{-6}\right) \mathrm{mol} \mathrm{dm}^{-3}$

$$
=1.0 \times 10^{-4} \mathrm{~mol} \mathrm{dm}^{-3}
$$

## Example 2.35

Consider a solution of $0.10 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{~A}^{2+}(\mathrm{aq})$ and $0.20 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{~B}^{3+}(\mathrm{aq})$.
$K_{\text {sp }}\left(\mathrm{AI}_{2}\right)=9.0 \times 10^{-9}$ and $K_{\text {sp }}\left(\mathrm{BI}_{3}\right)=1.6 \times 10^{-18}$
(i) What are the minimum concentration of $\mathrm{I}^{-}(\mathrm{aq})$ needed to start precipitation of the $\mathrm{A}^{2+}(\mathrm{aq})$ and $\mathrm{B}^{3+}(\mathrm{aq})$ ?
(ii) What range of concentrations of $\mathrm{I}^{-}(\mathrm{aq})$ can be used to precipitate only $\mathrm{B}^{3+}(\mathrm{aq})$ ?

## Answer

(i) For $\mathrm{AI}_{2}$

$$
\begin{aligned}
& \begin{aligned}
K_{\mathrm{sp}}= & {\left.\left[\mathrm{A}^{2+}(\mathrm{aq})\right]\left[\mathrm{I}^{-}(\mathrm{aq})\right]\right]^{2} }
\end{aligned} \\
& =\sqrt[2]{\frac{K_{\mathrm{sp}}}{\left[\mathrm{~A}^{2+}(\mathbf{a q})\right]}} \\
& \\
& \\
& =\sqrt[2]{\frac{\mathbf{9 . 0 \times 1 \mathbf { 1 0 } ^ { - 9 }}}{\mathbf{0 . 1 0}}} \\
& \\
& =3.0 \times 10^{-4} \mathrm{~mol} \mathrm{dm}^{-3}
\end{aligned}
$$

$$
\text { For } \mathrm{BI}_{3}
$$

$$
\begin{aligned}
& K_{\mathrm{sp}}=\left[\mathrm{B}^{3+}(\mathrm{aq})\right]\left[\mathrm{I}^{-}(\mathrm{aq})\right]^{3} \\
& {\left[\mathrm{I}^{-}(\mathrm{aq})\right]=\sqrt[3]{\frac{K_{\mathrm{sp}}}{\left[\mathrm{~B}^{3+}(\mathrm{aq})\right]}}} \\
& =\sqrt[3]{\frac{1.6 \times 10^{-18}}{0.20}} \\
& =2.0 \times 10^{-6} \mathrm{~mol} \mathrm{dm}^{-3}
\end{aligned}
$$

(ii) $2.0 \times 10^{-6} \mathrm{~mol} \mathrm{dm}^{-3}<\left[\mathrm{I}^{-}(\mathrm{aq})\right]<3.0 \times 10^{-4} \mathrm{~mol} \mathrm{dm}^{-3}$

### 2.4.5 Factors affecting solubility

## Common-ion effect

Consider the following equilibrium in a saturated solution of AgCl at 298 K .

$$
\mathrm{AgCl}(\mathrm{~s}) \rightleftharpoons \mathrm{Ag}^{+}(\mathrm{aq})+\mathrm{Cl}^{-}(\mathrm{aq})
$$

If $\left[\mathrm{Ag}^{+}(\mathrm{aq})\right]$ is increased, according to Le Chatelier principle the equilibrium will shift to left to keep the value of equilibrium constant, i. e. $K_{\text {sp }}$ constant. This increase of $\left[\mathrm{Ag}^{+}(\mathrm{aq})\right]$ can be achieved by adding a soluble salt like $\mathrm{AgNO}_{3}$ to the initial equilibrium. Because of this shift, more $\mathrm{AgCl}(\mathrm{s})$ is produced and hence the solubility of AgCl is decreased. This is called the "common-ion effect" because an ion that is already a part of the equilibrium (common to the equilibrium) is being added.

This can be stated as follows too.
If we cause the equilibrium to shift to the left then the rate of crystallization is increased more than the rate of dissolving. More $\mathrm{Ag}^{+}$ ions and $\mathrm{Cl}^{-}$ions will combine to form solid AgCl and its solubility decreases.

According to Le Chatelier's principle, the opposite is also true: if we can cause the equilibrium to shift to the right, then the rate of dissolution is increased more than the rate of crystallization and more solid AgCl will dissolve and its solubility increases.

## Example 2.36

Calculate the molar solubility of $\mathrm{Ni}(\mathrm{OH})_{2}$ in $0.10 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{NaOH}$.
$K_{\mathrm{sp}}\left(\mathrm{Ni}(\mathrm{OH})_{2}\right)=2.0 \times 10^{-15} \mathrm{~mol}^{3} \mathrm{dm}^{-9}$

## Answer

Let the solubility of $\mathrm{Ni}(\mathrm{OH})_{2}$ as $\boldsymbol{s}$.

$$
\mathrm{Ni}(\mathrm{OH})_{2}(\mathrm{~s}) \rightleftharpoons \mathrm{Ni}^{2+}(\mathrm{aq})+2 \mathrm{OH}^{-}(\mathrm{aq})
$$

At equilibrium :

$$
s \quad 2 s+0.10
$$

$K_{\mathrm{sp}}=\left[\mathrm{Ni}^{2+}(\mathrm{aq})\right]\left[\mathrm{OH}^{-}(\mathrm{aq})\right]^{2}$

$$
=s(2 s+0.10)^{2}
$$

As $K_{\text {sp }}$ is small, $(2 s \ll 0.10)$
$\therefore(2 s+0.10) \approx 0.10$
$2.0 \times 10^{-15} \mathrm{~mol}^{3} \mathrm{dm}^{-9}=\boldsymbol{s}(0.10)^{2}$
$s=2.0 \times 10^{-13} \mathrm{~mol} \mathrm{dm}^{-3}$
If we do not have a common ion solubility is $7.94 \times 10^{-6} \mathbf{~ m o l ~ d m}^{-3}$.

## Example 2.37

Calculate the molar solubility of $\mathrm{BaCrO}_{4}$ in (i) $0.100 \mathrm{~mol} \mathrm{dm}^{-3}$ and (ii) $1.00 \times 10^{-3} \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{BaCl}_{2}$ solutions at $298 \mathrm{~K} . K_{\mathrm{sp}}\left(\mathrm{BaCrO}_{4}\right)=1.2 \times 10^{-10} \mathrm{~mol}^{2} \mathrm{dm}^{-6}$.

## Answer

(i)

$$
\begin{aligned}
& \mathrm{BaCrO}_{4}(\mathrm{~s}) \rightleftharpoons \mathrm{Ba}^{2+}(\mathrm{aq})+\underset{s}{ }+\mathrm{CrO}_{4}{ }^{2-}(\mathrm{aq}) \\
& s+0.100
\end{aligned}
$$

At equilibrium :
$K_{\text {sp }}=\left[\mathrm{Ba}^{2+}(\mathrm{aq})\right]\left[\mathrm{CrO}_{4}{ }^{2-}(\mathrm{aq})\right]=(s+0.10) s$
As $K_{\text {sp }}$ is small, $(\boldsymbol{s} \ll 0.100)$
$\therefore(s+0.100) \approx 0.100$
$1.2 \times 10^{-10} \mathrm{~mol}^{2} \mathrm{dm}^{-6}=s(0.100)$
$s=1.2 \times 10^{-9} \mathbf{~ m o l ~ d m}^{-3}$
(ii)

$$
\mathrm{BaCrO}_{4}(\mathrm{~s}) \rightleftharpoons \mathrm{Ba}^{2+}(\mathrm{aq})+\mathrm{CrO}_{4}{ }^{2-}(\mathrm{aq})
$$

At equilibrium :

$$
s+0.001 \quad s
$$

$K_{\text {sp }}=\left[\mathrm{Ba}^{2+}(\mathrm{aq})\right]\left[\mathrm{CrO}_{4}{ }^{2-}(\mathrm{aq})\right]=(s+0.001) s$
As $\mathrm{K}_{\text {sp }}$ is small, ( $\mathrm{s} \ll 0.001$ )
$\therefore(s+0.001) \approx 0.001$
$1.2 \times 10^{-10} \mathrm{~mol}^{2} \mathrm{dm}^{-6}=s(0.001)$
$s=1.2 \times 10^{-7} \mathbf{m o l ~ d m}^{-\mathbf{3}}$
These results indicate that the solubility of $\mathrm{BaCrO}_{4}(\mathrm{~s})$ is comparatively high in dilute solutions of $\mathrm{BaCl}_{2}$.

## G.C.E. (A/L) CHEMISTRY: UNIT 12 Chemical Equilibrium

As we know that according to Le Chatelier's principle, if we can cause the equilibrium to shift to the right then the rate of dissolution is increased more than the rate of crystallization.

Consider the following equilibrium:

$$
\mathrm{PbCl}_{2}(\mathrm{~s}) \rightleftharpoons \mathrm{Pb}^{2+}(\mathrm{aq})+2 \mathrm{Cl}^{-}(\mathrm{aq})
$$

The solubility of the $\mathrm{PbCl}_{2}(\mathrm{~s})$ can be increased by decreasing either $\left[\mathrm{Pb}^{2+}(\mathrm{aq})\right]$ or $\left[\mathrm{Cl}^{-}\right.$ (aq)].
The $\left[\mathrm{Pb}^{2+}(\mathrm{aq})\right]$ can be decreased by adding some ion which precipitates the $\mathrm{Pb}^{2+}$. Any of the following ions: $\mathrm{Br}^{-}, \mathrm{I}^{-}, \mathrm{SO}_{4}{ }^{2-}, \mathrm{S}^{2-}, \mathrm{OH}^{-}, \mathrm{PO}_{4}{ }^{3-}, \mathrm{CO}_{3}{ }^{2-}, \mathrm{SO}_{3}{ }^{2-}$, will precipitate $\mathrm{Pb}^{2+}$. Even though there is a possibility to add any of the above anions, all of them may not decrease the $\left[\mathrm{Pb}^{2+}(\mathrm{aq})\right]$.

A new precipitate formed must have a lower solubility than that of the $\mathrm{PbCl}_{2}$. Therefore, for example, we can choose a soluble salt containing I- ions like KI because $K_{\text {sp }}$ of $\mathrm{PbI}_{2}$ is $1.4 \times 10^{-8} \mathrm{~mol}^{3} \mathrm{dm}^{-9}$ while $K_{\mathrm{sp}}$ of $\mathrm{PbCl}_{2}$ is $1.8 \times 10^{-5} \mathrm{~mol}^{3} \mathrm{dm}^{-9}$. Similarly, $\mathrm{AgNO}_{3}$ can be added to decrease the $\left[\mathrm{Cl}^{-}(\mathrm{aq})\right]$ which precipitates as AgCl .

## Example 2.38

Compare the relative solubility of $\mathrm{CaC}_{2} \mathrm{O}_{4}(\mathrm{~s})$ in $0.10 \mathrm{~mol} \mathrm{dm}^{-3}$ solutions of (i) NaOH , (ii) KCl and (iii) $\mathrm{Ca}\left(\mathrm{NO}_{3}\right)_{2}$

## Answer

As $\mathrm{CaC}_{2} \mathrm{O}_{4}(\mathrm{~s})$ is a spairingly soluble salt we can write,

$$
\mathrm{CaC}_{2} \mathrm{O}_{4}(\mathrm{~s}) \rightleftharpoons \mathrm{Ca}^{2+}(\mathrm{aq})+\mathrm{C}_{2} \mathrm{O}_{4}{ }^{2-}(\mathrm{aq})
$$

(i) $\mathrm{In} \mathrm{NaOH}(\mathrm{aq}): \mathrm{NaOH}(\mathrm{aq}) \rightarrow \mathrm{Na}^{+}(\mathrm{aq})+\mathrm{OH}^{-}(\mathrm{aq})$
$\mathrm{OH}^{-}(\mathrm{aq})$ will precipitate $\mathrm{Ca}^{2+}(\mathrm{aq})$ as $\mathrm{Ca}(\mathrm{OH})_{2}(\mathrm{~s})$
Thus, $\left[\mathrm{Ca}^{2+}(\mathrm{aq})\right]$ decreases, causing a shift to right, so the solubility of $\mathrm{CaC}_{2} \mathrm{O}_{4}(\mathrm{~s})$ increases.
(ii) $\operatorname{In~} \mathrm{KCl}(\mathrm{aq}): \mathrm{KCl}(\mathrm{aq}) \rightarrow \mathrm{K}^{+}(\mathrm{aq})+\mathrm{Cl}^{-}(\mathrm{aq})$
$\mathrm{K}^{+}(\mathrm{aq})$ and $\mathrm{Cl}^{-}(\mathrm{aq})$ will not affect the equilibrium.
(iii)In $\mathrm{Ca}\left(\mathrm{NO}_{3}\right)_{2}(\mathrm{aq}): \mathrm{Ca}\left(\mathrm{NO}_{3}\right)_{2}(\mathrm{aq}) \rightarrow \mathrm{Ca}^{2+}(\mathrm{aq})+2 \mathrm{NO}_{3}{ }^{-}(\mathrm{aq})$
$\mathrm{Ca}^{2+}(\mathrm{aq})$ is a common ion, so $\left[\mathrm{Ca}^{2+}(\mathrm{aq})\right]$ increases, causing a shift to left, forming more $\mathrm{CaC}_{2} \mathrm{O}_{4}(\mathrm{~s})$. Therefore the solubility of $\mathrm{CaC}_{2} \mathrm{O}_{4}$ decreases.

## G.C.E. (A/L) CHEMISTRY: UNIT 12 Chemical Equilibrium

### 2.4.6 pH effect

The solubility of many compounds depends strongly on the pH of the solution. For example, the anion in many sparingly soluble salts is the conjugate base of a weak acid that may become protonated in solution. In addition, the solubility of simple binary compounds such as oxides and sulfides, both strong bases, is often dependent on pH . For example consider the effect of pH on the solubility of a salt, MA where $\mathrm{A}^{-}$is the conjugate base of the weak acid HA. When the salt dissolves in water, the following reaction occurs:

$$
\mathrm{MA}(\mathrm{~s}) \rightleftharpoons \mathrm{M}^{+}(\mathrm{aq})+\mathrm{A}^{-}(\mathrm{aq}): \quad K_{\mathrm{sp}}=\left[\mathrm{M}^{+}(\mathrm{aq})\right]\left[\mathrm{A}^{-}(\mathrm{aq})\right] \ldots \ldots . .(1)
$$

The anion can also react with water in a hydrolysis reaction:

$$
\begin{equation*}
\mathrm{A}^{-}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{OH}^{-}(\mathrm{aq})+\mathrm{HA}(\mathrm{aq}) \tag{2}
\end{equation*}
$$

Because of the reaction described above, solubility of salt MA increases as the $\mathrm{A}^{-}(\mathrm{aq})$ produced in (1) is removed by reaction (2). For example predicted solubility of a sparingly soluble salt that has a basic anion such as $\mathrm{S}^{2-}, \mathrm{PO}_{4}{ }^{3-}$, or $\mathrm{CO}_{3}{ }^{2-}$ is increased. If instead a strong acid is added to the solution, the added $\mathrm{H}^{+}$will react almost completely with $\mathrm{A}^{-}$to form HA. This reaction decreases $\left[\mathrm{A}^{-}(\mathrm{aq})\right]$, which decreases the magnitude of the ionic product $\left(I P=\left[\mathrm{M}^{+}(\mathrm{aq})\right]\left[\mathrm{A}^{-}(\mathrm{aq})\right]\right)$. According to Le Chatelier's principle, more MA will dissolve until $I P=K_{\text {sp }}$. Hence an acidic $p H$ dramatically increases the solubility of virtually all sparingly soluble salts whose anion is the conjugate base of a weak acid.

Consider the following equilibrium:

$$
\mathrm{Ag}_{3} \mathrm{PO}_{4}(\mathrm{~s}) \rightleftharpoons 3 \mathrm{Ag}^{+}(\mathrm{aq})+\mathrm{PO}_{4}{ }^{3-}(\mathrm{aq})
$$

If $\mathrm{HNO}_{3}$ is added, the following reaction occurs:

$$
\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})+\mathrm{PO}_{4}{ }^{3-}(\mathrm{aq}) \rightleftharpoons \mathrm{HPO}_{4}{ }^{2-}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

This reaction reduces $\mathrm{PO}_{4}{ }^{3-}$ in solution, causing more solid $\mathrm{Ag}_{3} \mathrm{PO}_{4}$ to dissolve $\left(\mathrm{NO}^{3-}\right.$ ions remain in the solution as spectators without participating in any events).

Consider the following equilibrium:

$$
\mathrm{Cu}(\mathrm{OH})_{2}(\mathrm{~s}) \rightleftharpoons \mathrm{Cu}^{2+}(\mathrm{aq})+2 \mathrm{OH}^{-}(\mathrm{aq})
$$

- Increasing the pH means increasing $\left[\mathrm{OH}^{-}\right]$and equilibrium will shift to the left, causing some of $\mathrm{Cu}(\mathrm{OH})_{2}$ to precipitate out or decrease the solubility.
- If the pH is lowered, $\left[\mathrm{OH}^{-}\right]$decreases and equilibrium shifts to the right, causing solid $\mathrm{Cu}(\mathrm{OH})_{2}$ to dissolve or increase the solubility.
- The solubility of compounds of the type $\mathrm{M}(\mathrm{OH})_{\mathrm{n}}$ decreases as pH is increased, and increases as pH is decreased.

Thus, insoluble basic salts tend to dissolve in acidic solutions. Similarly, insoluble acidic solutions tend to dissolve in basic solutions.

## Example 2.39

Calculate the $\mathrm{Cu}^{2+}{ }_{(\mathrm{aq})}$ concentration in a saturated solution of $\mathrm{Cu}(\mathrm{OH})_{2}$ at 298 K , (i) when $\mathrm{pH}=10.0$ and (ii) when $\mathrm{pH}=5.0 . K_{\mathrm{sp}}\left(\mathrm{Cu}(\mathrm{OH})_{2}\right)=2.2 \times 10^{-20} \mathrm{~mol}^{3} \mathrm{dm}^{-9}$.

## Answer

(i) when $\mathrm{pH}=10.00$

$$
\begin{aligned}
& {\left[\mathrm{H}^{+}(\mathrm{aq})\right]=1.0 \times 10^{-10} \text { and }\left[\mathrm{OH}^{-}(\mathrm{aq})\right]=1.0 \times 10^{-4} \mathrm{~mol} \mathrm{dm}^{-3}} \\
& \\
& \text { At equilibrium: } \mathrm{Cu}(\mathrm{OH})_{2}(\mathrm{~s}) \rightleftharpoons \mathrm{Cu}^{2+}(\mathrm{aq})+2 \mathrm{OH}^{-}(\mathrm{aq}) \\
&
\end{aligned} \quad x \quad 1.0 \times 10^{-4} \mathrm{~mol} \mathrm{dm}^{-3} .
$$

$$
\begin{aligned}
K_{\mathrm{sp}} & =\left[\mathrm{Cu}^{2+}(\mathrm{aq})\right]\left[\mathrm{OH}^{-}(\mathrm{aq})\right]^{2}=2.2 \times 10^{-20} \mathrm{~mol}^{3} \mathrm{dm}^{-9} \\
& x\left(1.0 \times 10^{-4} \mathrm{~mol} \mathrm{dm}^{-3}\right)^{2}=2.2 \times 10^{-20} \\
\therefore x & =\left[\mathrm{Cu}^{2+}(\mathrm{aq})\right]=\mathbf{2 . 2} \times \mathbf{1 0}^{-\mathbf{1 2}} \mathbf{~ m o l ~ d m}
\end{aligned}
$$

(ii) when $\mathrm{pH}=5.00$

$$
\begin{aligned}
{\left[\mathrm{H}^{+}(\mathrm{aq})\right]=1.0 \times 10^{-5} \text { and }\left[\mathrm{OH}^{-}(\mathrm{aq})\right]=} & 1.0 \times 10^{-9} \mathrm{~mol} \mathrm{dm}^{-3} \\
\mathrm{Cu}(\mathrm{OH})_{2}(\mathrm{~s}) & \rightleftharpoons \mathrm{Cu}^{2+}(\mathrm{aq})+2 \mathrm{OH}^{-}(\mathrm{aq})
\end{aligned}
$$

$$
\text { At equilibrium : } \quad x \quad 1.0 \times 10^{-9}
$$

$$
\begin{aligned}
K_{\mathrm{sp}}= & {\left[\mathrm{Cu}^{2+}(\mathrm{aq})\right]\left[\mathrm{OH}^{-}(\mathrm{aq})\right]^{2}=2.2 \times 10^{-20} } \\
& x\left(1.0 \times 10^{-9} \mathrm{~mol} \mathrm{dm}^{-3}\right)^{2}=2.2 \times 10^{-20} \mathrm{~mol}^{3} \mathrm{dm}^{-9} \\
\therefore x= & {\left[\mathrm{Cu}^{2+}(\mathrm{aq})\right]=\mathbf{2 . 2} \times \mathbf{1 0}^{-\mathbf{2}} \mathbf{~ m o l ~ d m}^{-3} }
\end{aligned}
$$

We can note that decreasing pH increases the solubility of such metal hydroxides.

In the above example, the anion $\mathrm{OH}^{-}(\mathrm{aq})$ is derived from water and thus we could consider the effect of $\mathrm{H}^{+}(\mathrm{aq})$ in the medium. Such pH -dependent solubility is not restricted to salts that contain anions derived from water (metal hydroxides). For example, $\mathrm{CaF}_{2}$ is a sparingly soluble salt containing a basic anion: consider the equilibrium below at 298 K .

$$
\mathrm{CaF}_{2}(\mathrm{~s}) \rightleftharpoons \mathrm{Ca}^{2+}(\mathrm{aq})+2 \mathrm{~F}^{-}(\mathrm{aq}) ; \quad K_{\mathrm{sp}}=3.45 \times 10^{-11}
$$

When strong acid is added to a saturated solution of $\mathrm{CaF}_{2}$, the following reaction occurs.

$$
\mathrm{H}^{+}(\mathrm{aq}) \quad+\mathrm{F}^{-}(\mathrm{aq}) \rightleftharpoons \mathrm{HF}(\mathrm{aq})
$$

Because the forward reaction decreases the fluoride ion concentration, more $\mathrm{CaF}_{2}$ dissolves to relieve the stress on the system and the net reaction of $\mathrm{CaF}_{2}$ with strong acid is thus

$$
\mathrm{CaF}_{2}(\mathrm{~s})+2 \mathrm{H}^{+}(\mathrm{aq}) \rightarrow \mathrm{Ca}^{2+}(\mathrm{aq})+2 \mathrm{HF}(\mathrm{aq})
$$

## G.C.E. (A/L) CHEMISTRY: UNIT 12 Chemical Equilibrium

In another case of metal carbonates: $\mathrm{MCO}_{3}(\mathrm{~s})$

$$
\begin{aligned}
& \mathrm{MCO}_{3}(\mathrm{~s}) \rightleftharpoons \mathrm{M}^{2+}(\mathrm{aq})+\mathrm{CO}_{3^{2-}}(\mathrm{aq}) \\
& \mathrm{H}^{+}(\mathrm{aq})+\mathrm{CO}_{3}^{2-}(\mathrm{aq}) \rightleftharpoons \mathrm{HCO}_{3^{-}}(\mathrm{aq})
\end{aligned}
$$

The overall reaction is thus,

$$
\mathrm{MCO}_{3}(\mathrm{~s})+\mathrm{H}^{+}(\mathrm{aq}) \rightarrow \mathrm{M}^{2+}(\mathrm{aq})+\mathrm{HCO}_{3}^{-}(\mathrm{aq})
$$

i.e. More $\mathrm{MCO}_{3}(\mathrm{~s})$ dissolves to relieve the stress on the system which means that the increase in pH decreases the solubility while decrease in pH increases the solubility.

From the above, we can note that sparingly soluble salts derived from weak acids such as fluorides, oxalates, carbonates, phosphates, etc. tend to be more soluble in an acidic solution.

Consider the following example.
$\mathrm{PbC}_{2} \mathrm{O}_{4}, \mathrm{PbI}_{2}$ and $\mathrm{PbSO}_{4}$ are sparingly soluble salts with $K_{\text {sp }}$ values of $4.8 \times 10^{-10} \mathrm{~mol}^{2} \mathrm{dm}^{-6}, 9.8 \times 10^{-9} \mathrm{~mol}^{3} \mathrm{dm}^{-9}$ and $2.5 \times 10^{-5} \mathrm{~mol}^{2} \mathrm{dm}^{-6}$, respectively at 298 K. Compare their relative solubilities when a strong acid is added to saturated solutions of them.

We can write:

$$
\begin{aligned}
& \mathrm{PbC}_{2} \mathrm{O}_{4}(\mathrm{~s}) \rightleftharpoons \mathrm{Pb}^{2+}(\mathrm{aq})+\mathrm{C}_{2} \mathrm{O}_{4}{ }^{2-}(\mathrm{aq}) ; K_{\mathrm{sp}}=4.8 \times 10^{-10} \mathrm{~mol}^{2} \mathrm{dm}^{-6} \\
& \mathrm{PbI}_{2}(\mathrm{~s}) \rightleftharpoons \mathrm{Pb}^{2+}(\mathrm{aq})+2 \mathrm{I}^{-}(\mathrm{aq}) ; K_{\mathrm{sp}}=9.8 \times 10^{-9} \mathrm{~mol}^{3} \mathrm{dm}^{-9} \\
& \mathrm{PbSO}_{4}(\mathrm{~s}) \rightleftharpoons \mathrm{Pb}^{2+}(\mathrm{aq})+\mathrm{SO}_{4}{ }^{2-}(\mathrm{aq}) ; K_{\mathrm{sp}}=2.5 \times 10^{-5} \mathrm{~mol}^{2} \mathrm{dm}^{-6}
\end{aligned}
$$

The anions $\mathrm{C}_{2} \mathrm{O}_{4}{ }^{2-}, \mathrm{I}^{-}$, and $\mathrm{SO}_{4}{ }^{2-}$ formed in the above equilibria are all conjugate bases of acids $\mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}, \mathrm{HI}$, and $\mathrm{H}_{2} \mathrm{SO}_{4}$. Because the strongest conjugate base will be most affected by the addition of a strong acid, we can then relate the relative solubilities to their relative basicities.

Because HI is a strong acid, we predict that adding a strong acid to a saturated solution of $\mathrm{PbI}_{2}$ will not greatly affect its solubility; the acid will simply dissociate to form $\mathrm{H}^{+}(\mathrm{aq})$ and the corresponding anion.
$\mathrm{C}_{2} \mathrm{O}_{4}{ }^{2-}$ (aq) has high affinity for one proton and low affinity for a second proton. Therefore, addition of a strong acid to a saturated solution of $\mathrm{PbC}_{2} \mathrm{O}_{4}(\mathrm{~s})$ will result in the following reactions:

$$
\begin{gathered}
\mathrm{C}_{2} \mathrm{O}_{4}{ }^{2-}(\mathrm{aq})+\mathrm{H}^{+}(\mathrm{aq}) \rightleftharpoons \mathrm{HC}_{2} \mathrm{O}_{4}^{-}(\mathrm{aq}) \\
\text { and } \\
\mathrm{HC}_{2} \mathrm{O}_{4}^{-}(\mathrm{aq})+\mathrm{H}^{+}(\mathrm{aq}) \rightleftharpoons \mathrm{H}_{2} \mathrm{C}_{2} \mathrm{O}_{4}(\mathrm{aq})
\end{gathered}
$$

## G.C.E. (A/L) CHEMISTRY: UNIT 12 Chemical Equilibrium

These reactions will decrease $\left[\mathrm{C}_{2} \mathrm{O}_{4}{ }^{2-}(\mathrm{aq})\right]$, causing more lead oxalate to dissolve to relieve the stress on the system.

Adding a strong acid to a saturated solution of $\mathrm{PbSO}_{4}$ will result in the following reaction.

$$
\mathrm{SO}_{4}{ }^{2-}(\mathrm{aq})+\mathrm{H}^{+}(\mathrm{aq}) \rightleftharpoons \mathrm{HSO}_{4}^{-}(\mathrm{aq})
$$

The $\mathrm{p} K_{\mathrm{a}}$ of $\mathrm{HSO}_{4}{ }^{-}(\mathrm{aq})(1.99) \ll \mathrm{p} K_{\mathrm{a} 2}$ of oxalic acid, so the reverse reaction in the above equilibrium is largely favored. In other words, basicity of oxalic acid >>> basicity of sulfuric acid. Therefore, the effect of the strong acid added is significantly less on the solubility of $\mathrm{PbSO}_{4}$ than on $\mathrm{PbC}_{2} \mathrm{O}_{4}$.

From this example we can also note that the solubilities of salts containing anions (such as $\mathrm{Cl}^{-}, \mathrm{Br}^{-}, \mathrm{I}^{-}$) that do not hydrolyze are unaffected by $\mathbf{p H}$.

## Example 2.40

A sample has $3.0 \times 10^{-6} \mathrm{~mol} \mathrm{dm}^{-3}$ of $\mathrm{M}^{3+}(\mathrm{aq})$ in an acidic solution. To what pH must the solution be adjusted to begin precipitation of $\mathrm{M}^{3+}$ as $\mathrm{M}(\mathrm{OH})_{3}$ ?
$K s p=2.4 \times 10^{-20} \mathrm{~mol}^{4} \mathrm{dm}^{-12}$

## Answer

$$
K_{\mathrm{sp}}=\left[\mathrm{M}^{3+}(\mathrm{aq})\right]\left[\mathrm{OH}^{-}(\mathrm{aq})\right]^{3}=2.4 \times 10^{-20} \mathrm{~mol}^{4} \mathrm{dm}^{-12}
$$

$$
\left[\mathrm{OH}^{-}(\mathrm{aq})\right]=\sqrt[3]{\frac{2.4 \times 10^{-20}}{3.0 \times 10^{-6}}}=2.0 \times 10^{-5} \mathrm{~mol} \mathrm{dm}^{-3}
$$

$\therefore \mathrm{pOH}=4.7$
$\mathrm{pH}=9.3$
Thus, the solution will not begin to precipitate until enough base is added to adjust the pH to 9.3.

### 2.4.7 Application of solubility product in qualitative (cation) analysis

It is useful to know how to detect the presence of specific ions in an aqueous solution and the procedure used here comes under qualitative analysis, which addresses the question "What is in a sample?" The basis of qualitative analysis is the fact that ions will undergo specific chemical reactions with certain reagents to yield observable products. For example, silver ion can be precipitated with hydrochloric acid to yield insoluble solid silver chloride. Because many cations will not react with hydrochloric acid in this way, this simple reaction can be used to separate ions that form insoluble chlorides from those that do not. In fact, the qualitative detection of ions in a mixture is commonly accomplished by a systematic analysis in which precipitation reactions play a major role.

The various salts of the cations have varying solubilities in water. The differences in solubilities of these salts can be exploited in such a way as to allow for separation of the ions. For example, the addition of an appropriate chemical reagent to an aqueous mixture of cations can selectively cause one or more of the cations to form a precipitate while one or more of the cations will remain dissolved in water.

We know that cations can be separated into five major groups according to the solubilities of their compounds:

Group I $\left(\mathrm{Ag}^{+}, \mathrm{Pb}^{2+}, \mathrm{Hg}_{2}{ }^{2+}\right)$ cations produce insoluble chlorides so they can be precipitated with dilute HCl , while all other cations remain in solution.

Group II ( $\left.\mathrm{Cu}^{2+}, \mathrm{Bi}^{3+}, \mathrm{Cd}^{2+}, \mathrm{Hg}^{2+}, \mathrm{As}^{3+}, \mathrm{Sb}^{3+}, \mathrm{Sn}^{4+} / \mathrm{Sn}^{2+}\right)$ cations produce very insoluble sulfides ( $K_{\text {sp }}$ values less than $10^{-25}$ ) so they can be precipitated by low amounts of sulfide ion; this can be achieved by adding $\mathrm{H}_{2} \mathrm{~S}$ to an acidic solution of metal ions.

Group III ( $\mathrm{Al}^{3+}, \mathrm{Cr}^{3+}, \mathrm{Fe}^{2+}, \mathrm{Fe}^{3+}$ ) cations produce very insoluble hydroxides and they can be precipitated by adding relatively low amount of hydroxyl ions.

Group $\mathrm{IV}\left(\mathrm{Zn}^{2+}, \mathrm{Ni}^{2+}, \mathrm{Co}^{2+}, \mathrm{Mn}^{2+}\right.$ ) cations produce slightly soluble sulfides ( $K_{\mathrm{sp}}$ values more than $10^{-20}$ ) so they can be precipitated by relatively high amounts of sulfide ion; this can be achieved by adding $\mathrm{H}_{2} \mathrm{~S}$ to a basic solution of metal ions.

Group $V\left(\mathrm{Ca}^{2+}, \mathrm{Sr}^{2+}, \mathrm{Ba}^{2+}\right)$ cations, as well as all of the above groups, produce insoluble carbonates so they can be precipitated by the addition of carbonate once the ions of the first four groups have been removed.
$\left(\mathrm{Mg}^{2+}, \mathrm{Na}^{+}, \mathrm{K}^{+}, \mathrm{NH}_{4}^{+}\right)$cations do not precipitate with any of the above reagents.

## The chemistry of the precipitation of the Group I cations

The precipitating reagent of Group I is a dilute solution of hydrochloric acid ( 6 M ), and the ions precipitated are those of silver, $\mathrm{Ag}^{+}$, mercury (I), $\mathrm{Hg}_{2}{ }^{2+}$, and lead (II), $\mathrm{Pb}^{2+}$. The net ionic equations are:

$$
\begin{aligned}
& \mathrm{Ag}^{+}(\mathrm{aq})+\mathrm{Cl}^{-}(\mathrm{aq}) \rightarrow \mathrm{AgCl}(\mathrm{~s}) \\
& \mathrm{Hg}_{2}{ }^{2+}(\mathrm{aq})+2 \mathrm{Cl}^{-}(\mathrm{aq}) \rightarrow \mathrm{Hg}_{2} \mathrm{Cl}_{2}(\mathrm{~s}) \\
& \mathrm{Pb}^{2+}(\mathrm{aq})+2 \mathrm{Cl}^{-}(\mathrm{aq}) \rightarrow \mathrm{PbCl}_{2}(\mathrm{~s})
\end{aligned}
$$

A slight excess of chloride ion is used to reduce the solubility of the precipitates in accordance with the common ion effect. Even so the solubility of lead chloride is sufficiently high for an appreciable concentration of lead ion to remain in solution. Most of this is precipitated with the Group II reagent.

## The chemistry of the precipitation of the Group II cations

The ions of Group II (and Group IV) are separated by precipitation as their insoluble sulfides. The sulfide ion is furnished by the weak electrolyte of gaseous hydrogen sulfide, which is only sparingly soluble in water. At $25^{\circ} \mathrm{C}$ and 1 atmosphere pressure, a saturated aqueous solution contains about 0.1 mol in a litre). The dissolved molecular hydrogen sulfide dissociates into hydrogen ions, hydrogen sulfide ions, $\mathrm{HS}^{-}(\mathrm{aq})$, and sulfide ions, $\mathrm{S}^{2-}(\mathrm{aq})$ and we can consider the following equilibria.

Three equilibria are involved:

$$
\begin{gathered}
\mathrm{H}_{2} \mathrm{~S}(\mathrm{~g}) \rightleftharpoons \mathrm{H}_{2} \mathrm{~S}(\mathrm{aq}) \\
\mathrm{H}_{2} \mathrm{~S}(\mathrm{aq}) \rightleftharpoons \mathrm{H}^{+}(\mathrm{aq})+\mathrm{HS}^{-}(\mathrm{aq}) ; \quad K_{1}=\frac{\left[\mathrm{H}^{+}(\mathrm{aq})\right]\left[\mathrm{HS}^{-}(\mathrm{aq})\right]}{\left[\mathrm{H}_{2} \mathrm{~S}(\mathrm{aq})\right]}=9.1 \times 10^{-8} \mathrm{~mol} \mathrm{dm}^{-3} \\
\mathrm{HS}^{-}(\mathrm{aq}) \rightleftharpoons \mathrm{H}^{+}(\mathrm{aq})+\mathrm{S}^{2-}(\mathrm{aq}) ; \quad K_{2}=\frac{\left[\mathrm{H}^{+}(\mathrm{aq})\right]\left[\mathrm{s}^{2-}(\mathrm{aq})\right]}{\left[\mathrm{HS}^{-}(\mathrm{aq})\right]}=1.0 \times 10^{-19} \mathrm{~mol} \mathrm{dm}^{-3}
\end{gathered}
$$

The low value of $K_{2}$ suggests that there is very little free $\mathrm{S}^{2-}$ in aqueous solutions unless they are extremely basic. Therefore, the precipitation of metal sulfides is best written as:

$$
\mathrm{M}^{2+}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{~S}(\mathrm{aq}) \rightleftharpoons \mathrm{MS}(\mathrm{~s})+2 \mathrm{H}^{+}(\mathrm{aq})
$$

As with any equilibrium, the extent of reaction depends on the relative concentrations of products and reactants. In this case, making the solution acidic will tend to prevent precipitation of metal sulfides. Adding an acid shifts the above equilibrium to left. As The $K_{\text {sp }}$ values of group II metal ions is very low. Therefore sulfides of the metal ions with very low solubility will precipitate from acidic hydrogen sulfide solutions, while sulfides of greater solubility (Group IV) will remain in solution. Controlling the concentration of $\mathrm{H}^{+}(\mathrm{aq})$, therefore, can be used to separate ions on this basis of differences in the solubility of their sulfides. Group II is often called the acid hydrogen sulfide group in which the hydrogen ion concentration is maintained in the range of $0.1 \mathrm{~mol} \mathrm{dm}^{-3}$ $0.3 \mathrm{~mol} \mathrm{dm}^{-3}(\mathrm{pH}=0.5-1.0)$. By this the concentration of sulfide ions is so adjusted that only ionic products of the sulphides of group II exceed their solubility products and, therefore, get precipitated, but not the ions of group IV of which the sulfides are more soluble. These conditions can be achieved by passing $\mathrm{H}_{2} \mathrm{~S}(\mathrm{~g})$ into the filtrate from group I separation.

The reactions involved in the precipitation of Group II cations are as follows.

$$
\begin{aligned}
& \mathrm{Cu}^{2+}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{~S}(\mathrm{aq}) \rightarrow \mathrm{CuS}(\mathrm{~s})+2 \mathrm{H}^{+}(\mathrm{aq}) \\
& \mathrm{Cd}^{2+}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{~S}(\mathrm{aq}) \rightarrow \mathrm{CdS}(\mathrm{~s})+2 \mathrm{H}^{+}(\mathrm{aq}) \\
& \mathrm{Hg}^{2+}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{~S}(\mathrm{aq}) \rightarrow \mathrm{HgS}(\mathrm{~s})+2 \mathrm{H}^{+}(\mathrm{aq}) \\
& 2 \mathrm{Bi}^{3+}(\mathrm{aq})+3 \mathrm{H}_{2} \mathrm{~S}(\mathrm{aq}) \rightarrow \mathrm{Bi}_{2} \mathrm{~S}_{3}(\mathrm{~s})+6 \mathrm{H}^{+}(\mathrm{aq}) \\
& 2 \mathrm{As}^{3+}(\mathrm{aq})+3 \mathrm{H}_{2} \mathrm{~S}(\mathrm{aq}) \rightarrow \mathrm{As}_{2} \mathrm{~S}_{3}(\mathrm{~s})+6 \mathrm{H}^{+}(\mathrm{aq})
\end{aligned}
$$

$$
\begin{aligned}
& 2 \mathrm{Sb}^{3+}(\mathrm{aq})+3 \mathrm{H}_{2} \mathrm{~S}(\mathrm{aq}) \rightarrow \mathrm{Sb}_{2} \mathrm{~S}_{3}(\mathrm{~s})+6 \mathrm{H}^{+}(\mathrm{aq}) \\
& \mathrm{Sn}^{4+}(\mathrm{aq})+2 \mathrm{H}_{2} \mathrm{~S}(\mathrm{aq}) \rightarrow \mathrm{SnS}_{2}(\mathrm{~s})+4 \mathrm{H}^{+}(\mathrm{aq})
\end{aligned}
$$

## The chemistry of the precipitation of the Group III cations

$K_{\text {sp }}$ values of the hydroxides of group III cations are very low and hence they can be precipitated as hydroxide by controlling the concentration of hydroxide ions very low. In this separation care must be taken not to have the solution of hydrogen sulfide too basic. If the concentration of hydroxide ion is sufficiently high, unwanted precipitation of magnesium hydroxide will take place. To achieve a hydroxide ion concentration of the necessary concentration (about $1 \times 10^{-5} \mathrm{~mol} \mathrm{dm}^{-3}$ ) an ammonia-ammonium chloride $\left(\mathrm{NH}_{3}\right.$ / $\mathrm{NH}_{4} \mathrm{Cl}$ ) buffer is used. In the ammonia solution the following ionization equilibrium prevails:

$$
\begin{aligned}
& \mathrm{NH}_{3}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{NH}_{4}^{+}(\mathrm{aq})+\mathrm{OH}^{-}(\mathrm{aq}) \\
& \mathrm{NH}_{4} \mathrm{Cl}(\mathrm{aq}) \rightleftharpoons \mathrm{NH}_{4}^{+}(\mathrm{aq})+\mathrm{Cl}^{-}(\mathrm{aq})
\end{aligned}
$$

If $0.10 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{NH}_{3}$ solution is used, the hydroxide ion concentration will be $1.3 \times 10^{-3} \mathrm{~mol} \mathrm{dm}^{-3}$ which is sufficiently high to precipitate magnesium hydroxide. The presence of the added ammonium ion concentration from the ammonium chloride displaces the ammonia equilibrium to the left (common ion effect) reducing the hydroxide ion concentration. $\mathrm{A}\left[\mathrm{OH}^{-}(\mathrm{aq})\right]$ of about $1 \times 10^{-5} \mathrm{~mol} \mathrm{dm}^{-3}$ is sufficient to precipitate the slightly soluble aluminum and chromium hydroxides but not the more soluble magnesium hydroxide. We can understand this by comparing their $\mathrm{K}_{\text {sp }}$ values : $K_{\mathrm{sp}}\left(\mathrm{Al}(\mathrm{OH})_{3}\right)=1.8 \times$ $10^{-33} \mathrm{~mol}^{4} \mathrm{dm}^{-12}, K_{\mathrm{sp}\left(\mathrm{Cr}(\mathrm{OH})_{3}\right)}=3.0 \times 10^{-29} \mathrm{~mol}^{4} \mathrm{dm}^{-12}, K_{\mathrm{sp}\left(\mathrm{Fe}(\mathrm{OH})_{3}\right)}=1.4 \times 10^{-28} \mathrm{~mol}^{4} \mathrm{dm}^{-12}$ and $K_{\text {sp }}\left(\mathrm{Mg}(\mathrm{OH})_{2}\right)=1.8 \times 10^{-11} \mathrm{~mol}^{3} \mathrm{dm}^{-9}$.

The equations for the precipitation of the ions of Group III are:

$$
\begin{array}{ll}
\mathrm{Al}^{3+}(\mathrm{aq})+3 \mathrm{H}_{2} \mathrm{O}(\mathrm{aq})+3 \mathrm{NH}_{3}(\mathrm{aq}) & \rightarrow \mathrm{Al}(\mathrm{OH})_{3}(\mathrm{~s})+3 \mathrm{NH}_{4}^{+}(\mathrm{aq}) \\
\mathrm{Cr}^{3+}(\mathrm{aq})+3 \mathrm{H}_{2} \mathrm{O}(\mathrm{aq})+3 \mathrm{NH}_{3}(\mathrm{aq}) & \rightarrow \mathrm{Cr}(\mathrm{OH})_{3}(\mathrm{~s})+3 \mathrm{NH}_{4}^{+}(\mathrm{aq}) \\
\mathrm{Fe}^{3+}(\mathrm{aq})+3 \mathrm{H}_{2} \mathrm{O}(\mathrm{aq})+3 \mathrm{NH}_{3}(\mathrm{aq}) & \rightarrow \mathrm{Fe}(\mathrm{OH})_{3}(\mathrm{~s})+3 \mathrm{NH}_{4}^{+}(\mathrm{aq})
\end{array}
$$

At this stage, if the $\left[\mathrm{OH}^{-}(\mathrm{aq})\right]$ is high enough to precipitate $\mathrm{Mg}(\mathrm{OH})_{2}$

$$
\mathrm{Mg}^{2+}(\mathrm{aq})+\mathrm{OH}^{-}(\mathrm{aq}) \rightarrow \mathrm{Mg}(\mathrm{OH})_{2}(\mathrm{~s})
$$

Therefore, control of $\mathrm{OH}^{-}$concentration is a must in the separation of $\mathrm{Al}^{3+}, \mathrm{Cr}^{3+}$ and $\mathrm{Fe}^{3+}$ without the precipitation of $\mathrm{Mg}^{2+}$ ions.

## The chemistry of the precipitation of the Group IV cations

The ions of Group IV are precipitated as their sulfides, from a basic solution of hydrogen sulfide. In a basic solution, more of the ionization of $\mathrm{H}_{2} \mathrm{~S}$ occurs and, thus, concentration of $\mathrm{S}^{2-}$ ions increases. It becomes so high that ionic products of the sulphides of group IV exceed their solubility products and they get precipitated.

$$
\begin{aligned}
& \mathrm{H}_{2} \mathrm{~S}(\mathrm{~g}) \rightleftharpoons \mathrm{H}_{2} \mathrm{~S}(\mathrm{aq}) \\
& \mathrm{H}_{2} \mathrm{~S}(\mathrm{aq}) \rightleftharpoons 2 \mathrm{H}^{+}(\mathrm{aq})+\mathrm{S}^{2-}(\mathrm{aq})
\end{aligned}
$$

In the presence of $\mathrm{OH}^{-}(\mathrm{aq})$ ions, the $\mathrm{H}^{+}(\mathrm{aq})$ ions are neutralized and therefore the solution contains fairly high concentration of $\mathrm{S}^{2-}(\mathrm{aq})$ ions enough to precipitate group IV cations as their sulfides.The sulfides of the ions of group IV are not sufficiently insoluble to be precipitated in the acidic solution of hydrogen sulfide of Group II but will be precipitated by basic solutions of hydrogen sulfide. The equations for the precipitation of the ions of Group IV are:

$$
\begin{aligned}
& \mathrm{Zn}^{2+}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{~S}(\mathrm{aq}) \rightarrow \mathrm{ZnS}(\mathrm{~s})+2 \mathrm{H}^{+}(\mathrm{aq}) \\
& \mathrm{Ni}^{2+}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{~S}(\mathrm{aq}) \rightarrow \mathrm{NiS}(\mathrm{~s})+2 \mathrm{H}^{+}(\mathrm{aq}) \\
& \mathrm{Co}^{2+}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{~S}(\mathrm{aq}) \rightarrow \mathrm{CoS}(\mathrm{~s})+2 \mathrm{H}^{+}(\mathrm{aq}) \\
& \mathrm{Mn}^{2+}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{~S}(\mathrm{aq}) \rightarrow \mathrm{MnS}(\mathrm{~s})+2 \mathrm{H}^{+}(\mathrm{aq})
\end{aligned}
$$

## The chemistry of the precipitation of the Group $V$ cations

The ions of Group V are precipitated as their carbonates in basic solution. This condition is achieved by removing $\mathrm{H}_{2} \mathrm{~S}\left(\right.$ (aq) in filtrate from group IV by boiling and adding $\mathrm{NH}_{4} \mathrm{Cl} /$ $\mathrm{NH}_{4} \mathrm{OH}$ in excess. Adding $\left(\mathrm{NH}_{4}\right)_{2} \mathrm{CO}_{3}$ solution will enable the precipitation of group V cations. The equations for the precipitation of the ions of Group V are:

$$
\begin{aligned}
& \mathrm{Ca}^{2+}(\mathrm{aq})+\mathrm{CO}_{3}^{2-}(\mathrm{aq}) \rightarrow \mathrm{CaCO}_{3}(\mathrm{~s}) \\
& \mathrm{Sr}^{2+}(\mathrm{aq})+\mathrm{CO}_{3}{ }^{2-}(\mathrm{aq}) \rightarrow \mathrm{SrCO}_{3}(\mathrm{~s}) \\
& \mathrm{Ba}^{2+}(\mathrm{aq})+\mathrm{CO}_{3}{ }^{2-}(\mathrm{aq}) \rightarrow \mathrm{BaCO}_{3}(\mathrm{~s})
\end{aligned}
$$

## The chemistry of the precipitation of the Group VI cations

Magnesium : If only $\mathrm{Mg}^{2+}$ ions present in a solution it is easy to identify by simple tests. However, in a mixture of cations, it is difficult to identify and therefore, a specific test with 8 -hydroxyquinoline is carried out to identify $\mathrm{Mg}^{2+}$ by precipitation which forms a yellow-green precipitate or complex.
$\mathrm{Na}^{+}, \mathrm{K}^{+}, \mathrm{NH}_{4}{ }^{+}$cations do not precipitate with any of the above reagents and usually identified by the flame test by the observation of their characteristic colors in the flame.

The following example explains the importance of pH in selective precipitation.

## Example 2.41

A solution contains $0.1 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{Zn}^{2+}$ and $0.1 \mathrm{~mol} \mathrm{dm}{ }^{-3} \mathrm{Fe}^{2+}$ ions. What should be the $p \mathrm{H}$ of the solution, if they are to be separated by passing $\mathrm{H}_{2} \mathrm{~S}$ gas through the solution?
Given that $K_{s p}$ for $\mathrm{ZnS}=1.6 \times 10^{-24} \mathrm{~mol}^{2} \mathrm{dm}^{-6}$ and $\mathrm{K}_{\mathrm{sp}}$ for $\mathrm{FeS}=6.3 \times 10^{-18} \mathrm{~mol}^{2} \mathrm{dm}^{-6}$. In a solution $\mathrm{H}_{2} \mathrm{~S}(\mathrm{aq})$ has a concentration of $0.10 \mathrm{~mol} \mathrm{dm}^{-3}$.

## Answer

When $\mathrm{H}_{2} \mathrm{~S}(\mathrm{~g})$ is passed through a solution following equilibria exist.

$$
\begin{aligned}
& \mathrm{H}_{2} \mathrm{~S}(\mathrm{~g}) \rightleftharpoons \mathrm{H}_{2} \mathrm{~S}(\mathrm{aq}) \\
& \mathrm{H}_{2} \mathrm{~S}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})+\mathrm{HS}(\mathrm{aq}) ; K_{\mathrm{a}_{1}}=\frac{\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]\left[\mathrm{HS} \mathrm{~S}^{-}(\mathrm{aq})\right]}{\left.\left[\mathrm{H}_{2} \mathrm{Saq}\right)\right]} \\
&=99.1 \times 10^{-8} \mathrm{~mol} \mathrm{dm} \\
& \\
& \mathrm{HS}^{-}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})+\mathrm{S}^{2-}(\mathrm{aq}) ; K_{\mathrm{a}_{2}}=\frac{\left[\mathrm { H } _ { 3 } \mathrm { 0 } ^ { + } ( \mathrm { aq } ) \left[\mathrm{s}^{2-(a q q)]}\right.\right.}{\left[\mathrm{HS}^{-}(\mathrm{aqq)]}\right.} \\
&=1.0 \times 10^{-19} \mathrm{~mol} \mathrm{dm}
\end{aligned}
$$

From these two equations we can write

$$
K_{\mathrm{a}_{1}} K_{\mathrm{a}_{2}}\left[\mathrm{H}_{2} \mathrm{~S}(\mathrm{aq})\right]=\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]^{2}\left[\mathrm{~s}^{2-}(\mathrm{aq})\right]
$$

Substituting the given, we get,

$$
\begin{aligned}
{\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]^{2}\left[\mathrm{~S}^{2-}(\mathrm{aq})\right] } & =\left(9.1 \times 10^{-8}\right)\left(1.0 \times 10^{-19}\right)(0.1) \mathrm{mol}^{3} \mathrm{dm}^{-9} \\
& =9.1 \times 10^{-28} \mathrm{~mol}^{3} \mathrm{dm}^{-9}
\end{aligned}
$$

From the given data, we have,
$K_{\mathrm{sp}}(\mathrm{ZnS})=\left[\mathrm{Zn}^{2+}(\mathrm{aq})\right]\left[\mathrm{S}^{2-}(\mathrm{aq})\right]=1.6 \times 10^{-24} \mathrm{~mol}^{2} \mathrm{dm}^{-6}$ and $K_{\mathrm{sp}}(\mathrm{FeS})=\left[\mathrm{Fe}^{2+}(\mathrm{aq})\right]\left[\mathrm{S}^{2-}(\mathrm{aq})\right]=6.3 \times 10^{-18} \mathrm{~mol}^{2} \mathrm{dm}^{-6}$

In case when $\left[\mathrm{Zn}^{2+}(\mathrm{aq})\right]=0.1 \mathrm{~mol} \mathrm{dm}{ }^{-3}$, minimum $\left[\mathrm{S}^{2-}(\mathrm{aq})\right]$ required for precipitating ZnS can be calculated as,
$\left[\mathrm{S}^{2-}(\mathrm{aq})\right]=\frac{1.6 \times 10^{-24}}{0.1}=1.6 \times 10^{-23} \mathrm{~mol} \mathrm{dm}^{-3}$
Corresponding to this minimum concentration of $\mathrm{S}^{2-}$ ions we can calculate the maximum $\mathrm{H}_{3} \mathrm{O}^{+}$concentration by using the following equation

$$
\begin{gathered}
{\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]^{2}\left[\mathrm{~S}^{2-}(\mathrm{aq})\right]=9.1 \times 10^{-28} \mathrm{~mol}^{3} \mathrm{dm}^{-9}} \\
\therefore\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]^{2}=\frac{9.1 \times 10^{-28}}{1.6 \times 10^{-23}}=5.7 \times 10^{-5} \mathrm{~mol}^{2} \mathrm{dm}^{-6} \\
\therefore\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]=7.6 \times 10^{-3} \mathrm{~mol} \mathrm{dm}^{-3} \\
\therefore \mathrm{pH}=-\log \left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]=2.1
\end{gathered}
$$

$\therefore$ The minimum pH required for precipitation of $\mathrm{ZnS}=2.1$

## G.C.E. (A/L) CHEMISTRY: UNIT 12 Chemical Equilibrium

Likewise in case when $\left[\mathrm{Fe}^{2+}(\mathrm{aq})\right]=0.1 \mathrm{~mol} \mathrm{dm}{ }^{-3}$
Minimum $\left[\mathrm{S}^{2-}(\mathrm{aq})\right]$ required for precipitating FeS is,

$$
\left[\mathrm{S}^{2-}(\mathrm{aq})\right]=\frac{6.3 \times 10^{-18}}{0.1}=6.3 \times 10^{-17} \mathrm{~mol} \mathrm{dm}^{-3}
$$

And the maximum $\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]$ required is given by,

$$
\begin{gathered}
\therefore\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]^{2}=\frac{9.1 \times 10^{-28}}{6.3 \times 10^{-17}}=1.4 \times 10^{-11} \mathrm{~mol}^{2} \mathrm{dm}^{-6} \\
\therefore\left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]=3.7 \times 10^{-6} \mathrm{~mol} \mathrm{dm}^{-3} \\
\therefore \mathrm{pH}=-\log \left[\mathrm{H}_{3} \mathrm{O}^{+}(\mathrm{aq})\right]=5.4
\end{gathered}
$$

Therefore, the minimum pH at which FeS precipitates $=5.4$
It is seen that if the $\mathrm{H}_{3} \mathrm{O}^{+}$ion concentration is higher than $10^{-5.4} \mathrm{~mol} \mathrm{dm}^{-3}(3.7 \times$ $10^{-6} \mathrm{~mol} \mathrm{dm}{ }^{-3}$ ), $\mathrm{Fe}^{2+}$ will not be precipitated whereas $\mathrm{Zn}^{2+}$ will get precipitated.

The pH of the solution to separate the two ions should be between 2.1 and 5.4.

### 2.5 Equilibria in different phases

As we already have an idea that the matter exists in three phases solid, liquid and gas and when the matter undergoes phase changes (transformations) from one phase to another macroscopic properties of the system remain unchanged while microscopic properties change. Usually, phase changes occur when the temperature or pressure of the system is changed and the phase changes are physical changes characterized by changes in molecular order; molecules in the solid phase have the greatest order, and those in the gas phase have the greatest randomness. In this section, we deal with systems having liquid - vapour equilibrium.

## Liquid- vapour equilibrium

Molecules in a liquid are not arranged tidily as those in a solid and therefore they have lesser freedom than those of gaseous molecules, though they are in constant motion. Because liquids have higher intermolecular attractions than gases, the collision rate among molecules is much higher in the liquid phase than in the gas phase. The average energy of the particles in a liquid is governed by the temperature as shown in Figure 2.29. When the molecules in a liquid have sufficient energy to escape from the surface a phase change occurs. Evaporation, or vapourization, is the process in which a liquid is transformed into a gas.

Figure 2.29 The distribution of the kinetic energies of the molecules of a liquid at two temperatures of 300 K and 400 K . Increasing the temperature shifts the peak to a higher energy and broadens the curve. Only molecules with a kinetic energy greater than $E_{\text {evap }}$ can escape from the liquid to enter the vapour phase, and the proportion of molecules with $K E>E_{\text {evap }}$ is greater at the higher temperature.

For example, when we consider a liquid (water or alcohol) in an open container, at any given instant a small fraction of the molecules in the liquid phase will be moving quite fast. If one of these is close to the surface and is travelling upward, it can escape from the attraction with its fellow molecules entirely and pass into the gas phase. As the higher energy molecules depart, the average energy of the molecules in the liquid decreases and the temperature of the liquid falls due to the absorption of energy in the form of heat by the surroundings, an effect which you can feel if you let water or alcohol to evaporate from your skin. Absorption of heat maintains the average molecular speed in the liquid, so that, given enough time, all the liquid can evaporate. The heat absorbed during the entire process corresponds to the enthalpy of vapourization. The evaporation only takes place on the surface of the liquid. If we look at water which is just evaporating in the sun, we don't see any bubbles. Water molecules are simply breaking away from the surface layer and the process is different from boiling where we observe bubbling.This is illustrated in Figure 2.30.

Figure 2.30 Patter of evaporation of a liquid in an open container at a given temperature. Most of the molecules with high energy that escape into the vapour phase will not collide with the surface of the liquid again and return to the liquid phase. Instead, they will diffuse through the gas phase away from the container.

### 2.5.1 Evaporation of a liquid in a closed container

If the liquid is in a closed container, at the first look it doesn't seem to evaporate and also it doesn't disappear over time. But there is constant evaporation from the surface. Particles continue to break away from the surface of the liquid but this time they are trapped in the space above the liquid.

Figure 2.31 Macroscopic view of the molecular interpretation of vapour pressure. When a liquid is placed in a closed container at a given temperature, few molecules start to evaporate at the beginning and none of them can come back and re-enter into the liquid. After some time the density of the molecules in the vapour phase becomes high and some of the molecules start to condense.

On the microscopic level, though molecules are still escaping from the liquid surface into the vapour above, the vapour remains inside the container. Molecules of the vapour behave like any other gas: they bounce around colliding with each other and the walls of the container and hence producing a pressure above the liquid surface. In this case one of these "walls" is the surface of the liquid. Once a molecule collides with the liquid surface there is a tendency that the molecule will re-enter into the liquid.

When the liquid is first introduced into the container, there are very few molecules of vapour and the rate of recapture/ condensation will be quite low, but as more and more molecules evaporate, the chances of a recapture will become proportionately larger. Eventually the vapour pressure will be attained, and the rate of recapture will exactly balance the rate of escape. There will then be no net evaporation of liquid or condensation of gas. i.e. the amount of vapour remains the same only because molecules are reentering the liquid just as fast as they are escaping from it.

Once the vapour-liquid system has attained this state, the macroscopic properties such as the amount, the volume, the pressure, the temperature, the density, etc., of both liquid and gas will all remain constant with time and therefore the system has attained an equilibrium. As there is no change in the macroscopic level of the system, the two opposing microscopic processes of vaporization and condensation occur with equal rates.

Since both microscopic processes are still in operation, the system is in dynamic equilibrium. When these particles hit the walls of the container, they exert a pressure. The pressure exerted by a vapour in dynamic equilibrium with a liquid is defined as the equilibrium vapor pressure of the liquid (sometimes called the saturated vapour pressure of the liquid). This process is shown in Figure 2.32 where we have to note that the evaporation rate is constant over the time and the rate of condensation increases with time and reaches the equilibrium.

Figure 2.32 Variation of the rates of evaporation and condensation over the time for a liquid in a closed container at a given temperature. Rate of evaporations remains a constant while the rate of condensataion increases as the number of molecules in the vapour phase increases till the two rates become equal. At this point the system reaches a state of dynamic equilibrium having the equilibrium vapour pressure of the liquid at a constant temperature.

The magnitude of the vapour pressure of a liquid depends mainly on two factors: the strength of the forces holding the molecules together and the temperature. It is easy to see that if the intermolecular forces are weak, the vapour pressure will be high and vice versa. Weak intermolecular forces will permit molecules to escape relatively easily from the liquid. The rate at which molecules escape will thus be high. Quite a large concentration of molecules will have to build up in the gas phase before the rate of re-entry can balance the escape rate. Consequently the vapour pressure will be large.

### 2.5.2 Measuring the equilibrium (saturated) vapour pressure

The equilibrium vapour pressure can be measurd with a simple mercury - barometer as described below. At the atmosphere pressure the height of the mercury column will be 760 mm . [ $100 \mathrm{kPa}=760 \mathrm{mmHg}$ ("millimetres of mercury")]. This is illustrated in Figure 2.33 (a). When a few drops of liquid is added into the tube, it will rise to form a thin layer floating on top of the mercury. Some of the liquid will vapourize and the equilibrium is attained. At this point some liquid will remain on top of the mercury. The vapour pressure of the liquid forces the mercury level down a bit. The drop in the mecury level gives a value for the saturated vapour pressure of the liquid at this temperature.

Figure 2.33 Measuring the saturated vapour pressure. (a) when a mecury barometer is just in air, the reading is 760 mmHg . (b) when a liquid is introduced into the tube, it goes on to the top of the mecury in a barometer and the level of Hg falls down. The difference is the saturated vapour pressure of the liquid.

### 2.5.3 The variation of saturated vapour pressure with temperature

Increase in the temperature increases the average energy of the molecules present. That means, more of them are likely to have enough energy to escape from the surface of the liquid. That will tend to increase the saturated vapour pressure.

Figure 2.34 Variation of the saturated vapour pressure of water with temperature.
For example, any size sample of water held at $25^{\circ} \mathrm{C}$ will produce a vapour pressure of $23.8 \mathrm{mmHg}(3.168 \mathrm{kPa})$ in any closed container, provided all the water does not evaporate.

If a liquid is in an open container, however, most of the molecules that escape into the vapour phase will not collide with the surface of the liquid and return to the liquid phase. Instead, they will diffuse through the gas phase away from the container, and the equilibrium will never be established. Under these conditions, the liquid will continue to evaporate until it "disappears". The speed with which this occurs depends on the vapour pressure of the liquid and the temperature. Volatile liquids have relatively high vapour pressures and tend to evaporate readily; nonvolatile liquids have low vapor pressures and
evaporate slowly. As a general guideline, we consider that substances with vapour pressures greater than that of water $(3.168 \mathrm{kPa})$ are relatively volatile, whereas those with vapour pressures less than that of water are relatively nonvolatile. Thus diethyl ether, acetone, and gasoline are volatile, but mercury, ethylene glycol, etc. are non-volatile. The equilibrium vapour pressure of a substance at a particular temperature is a characteristic of the material, like its molecular mass, melting point, and boiling point. It does not depend on the amount of liquid as long as at least a tiny amount of liquid is present in equilibrium with the vapor. The equilibrium vapour pressure does, however, depend very strongly on the temperature and the intermolecular forces present, as shown for several substances in Figure 2.35. Molecules that can have hydrogen bonds, such as ethylene glycol, have a much lower equilibrium vapour pressure than those that cannot make hydrogen bonds, such as octane. The non-linear increase in vapour pressure with increasing temperature is much steeper than the increase in pressure expected for an ideal gas over the corresponding temperature range. This is mainly due to the dependence of vapour pressure on the fraction of molecules that have a kinetic energy greater than that needed to escape from the liquid phase, and this fraction increases exponentially with temperature.

Figure 2.35 The vapour pressures of several liquids as a function of temperature. The point at which the vapour pressure curve crosses the $\mathrm{P}=100 \mathrm{kPa}$ line (dotted) is the normal boiling point of the liquid.

### 2.5.4 Boiling point

As the temperature of a liquid increases, the vapour pressure of the liquid increases until it equals the external pressure, or the atmospheric pressure in the case of an open container. Bubbles of vapour begin to form throughout the liquid, and the liquid begins to boil. The temperature at which a liquid boils at exactly 100 kPa (1atm) pressure is the normal boiling point of the liquid. For water, the normal boiling point is exactly $100^{\circ} \mathrm{C}$ at the sea level. The normal boiling points of the other liquids in Figure 2.35 are represented by the points at which the vapour pressure curves cross the line corresponding to a pressure of 1 atm .

## G.C.E. (A/L) CHEMISTRY : UNIT 12 <br> Chemical Equilibrium

Although we usually cite the normal boiling point of a liquid, the actual boiling point depends on the pressure. At a pressure greater than $100 \mathrm{kPa}(1 \mathrm{~atm})$, water boils at a temperature greater than $100^{\circ} \mathrm{C}$ because the increased pressure forces vapour molecules above the surface to condense. Hence the molecules must have greater kinetic energy to escape from the surface. Conversely, at pressures less than 100 kPa ( 1 atm ), water boils below $100^{\circ} \mathrm{C}$. Typical variations in atmospheric pressure at sea level are relatively small, causing only minor changes in the boiling point of water. At high altitudes, on the other hand, the dependence of the boiling point of water on pressure becomes significant. At an elevation of Mount Everest, for example, the boiling point of water is about $70^{\circ} \mathrm{C}$. However, in the case of pressure cookers, which have a seal that allows the pressure inside them to exceed 100 kPa (upto around $200 \mathrm{kPa} / 2 \mathrm{~atm}$ ), are used to cook food more rapidly by raising the boiling point of water to around $120^{\circ} \mathrm{C}$ and thus the temperature at which the food is being cooked.

As pressure increases, the boiling point of a liquid increases and vice versa. Volatile substances have low boiling points and relatively weak intermolecular interactions; non-volatile substances have high boiling points and relatively strong intermolecular interactions.

Figure 2.36 Change in boiling point of water with the pressure: water boils at normal boling point of $100{ }^{\circ} \mathrm{C}$ at atmospheric pressure of 100 kPa , boiling of water occurs at around $79^{\circ} \mathrm{C}$ at mountain top and the boiling temperature increses to around $121^{\circ} \mathrm{C}$ when it boils inside a pressure cooker.

## Example 2.42

Compare the variation in relative vapour pressures of ethanol, ethelene glycol, diethyl eather and water at 100 kPa pressure and room temperature.

## Answer

First, we have to know the structures of these compounds and we have,

Diethyl ether: is the largest, however, it has a very small dipole and its intermolecular attractions are London forces. As a result, its molecules most readily escape from the liquid. It also has the highest vapour pressure.

Ethanol: Due to its smaller size, ethanol exhibits weaker dispersion forces than diethyl ether. It has a capability to form hydrogen bonds. Therefore it exhibits stronger overall intermolecular forces, which means that fewer molecules escape from the liquid at any given temperature, so ethanol has a lower vapour pressure than diethyl ether.

Water: is much smaller than either of the previous substances and exhibits weaker dispersion forces, but its extensive hydrogen bonding provides stronger intermolecular attractions, fewer molecules escaping the liquid, and a lower vapour pressure than in either diethyl ether or ethanol.

Ethylene glycol: has two - OH groups like water and therefore, it exhibits extensive hydrogen bonding. It is much larger than water and thus experiences larger London forces. Its overall intermolecular forces are the largest of these four substances, which means its vapourization rate will be the slowest and, consequently, its vapour pressure being the lowest.

Therefore, the variation in vapour pressure is in the order, diethyl eather > ethanol > water > ethelene glycol

## Example 2.43

At $20^{\circ} \mathrm{C}$, the vapour pressures of methanol, ethanol, propanol and butanol are $12.0 \mathrm{kPa}, 6.0 \mathrm{kPa}, 2.7 \mathrm{kPa}$ and 0.60 kPa , respectively. Explain this variation.

## Answer

All of these are alcohols and exhibit hydrogen bonding. As the size of molecule increases from methanol to butanol, dispersion forces increase, which means that the vapor pressures decrease as observed.

$$
P_{\text {methanol }}>P_{\text {ethanol }}>P_{\text {propanol }}>P_{\text {butanol }}
$$

### 2.5.5 Enthalpy of vapourization

Vapourization is an endothermic process. This can be understood with a simple phenomenon of our own. When water on the skin evaporates, it removes heat from the body and causes to feel cold. The energy change associated with the vapourization process is the enthalpy of vapourization, $\Delta H_{\text {vap }}$. For example, the vapourization of water at standard temperature is represented by:

$$
\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightarrow \mathrm{H}_{2} \mathrm{O}(\mathrm{~g}) \quad \Delta H_{\text {vap }}=44.01 \mathrm{~kJ} \mathrm{~mol}^{-1}
$$

As described in the chapter on thermochemistry, the reverse of an endothermic process is exothermic. And so, the condensation of a gas releases heat:

$$
\mathrm{H}_{2} \mathrm{O}(\mathrm{~g}) \rightarrow \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \quad \Delta H_{\text {con }}=-44.01 \mathrm{~kJ} \mathrm{~mol}^{-1}
$$

## Example 2.44

At normal body temperature, how much heat is required when $1.5 \mathrm{dm}^{3}$ of water (as sweat) is evaporated from the body? $\Delta H_{\text {vap }}=43.46 \mathrm{~kJ} \mathrm{~mol}^{-1}$ at $37^{\circ} \mathrm{C}$.

## Answer

Weight of $1.5 \mathrm{dm}^{3}$ of water $=1.5 \mathrm{dm}^{3} \times 1000 \mathrm{~g} \mathrm{dm}^{-3}=1.5 \times 10^{3} \mathrm{~g}$
$\therefore$ Amount of moles of water evaporated $=1.5 \times 10^{3} \mathrm{~g} /\left(18 \mathrm{~g} \mathrm{~mol}^{-1}\right)=83.333 \mathrm{~mol}$
$\therefore$ Heat required $=43.46 \mathrm{~kJ} \mathrm{~mol}^{-1} \times 83.333 \mathrm{~mol}=3621 \mathrm{~kJ}^{2}$

In the sequel other phase changes of a single component system are also described as they are essential in understanding the behaviour of them in the light of getting knowledge of energy/ enthalpy changes during such events in chemical processes.

## Melting and Freezing

When a crystalline solid is heatd, the average energy of its atoms is increased and molecules or ions and the solid get some kinetic energy. At some point, when the added energy/ heat becomes large enough to partially overcome the forces holding the molecules or ions together, the solid starts the process of transition to the liquid state, or melting. At this point, despite the continuous heating the temperature remains constant until the entire solid is melted. After all of the solid has melted the temperature of the liquid then increases if the heating is continued.

For example, if we stop heating during melting and place the mixture of solid and liquid in a perfectly insulated container, the solid and liquid phases remain in equilibrium. This can be observed experimentally when a mixture of ice and water is kept in a thermos flask and we can observe that the mixture of solid ice and liquid water remains for hours. At this point the mixture of solid and liquid is at equilibrium and the reciprocal processes of melting of ice and freezing of water occur at equal rates, and the quantities of solid and liquid therefore remain constant. The temperature at which the solid and liquid phases of a given substance are in equilibrium is called the melting point of the solid or the freezing point of the liquid. This equilibrium is expressed as:

$$
\text { Solid } \underset{\text { freezing }}{\stackrel{\text { melting }}{\rightleftharpoons} \text { Liquid }}
$$

The amount of heat required to change one mole of a substance from the solid state to the liquid state is the enthalpy of fusion, $\Delta \boldsymbol{H}_{\text {fus }}$ of the substance. The enthalpy of fusion (melting) of ice is $6.0 \mathrm{~kJ} \mathrm{~mol}^{-1}$ at $0^{\circ} \mathrm{C}$ and is an endothermic process:

$$
\mathrm{H}_{2} \mathrm{O}(\mathrm{~s}) \rightarrow \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \quad \Delta H_{\mathrm{fus}}=6.0 \mathrm{~kJ} \mathrm{~mol}^{-1}
$$

The opposite process, freezing, is an exothermic process whose enthalpy change is -6.0 $\mathrm{kJ} \mathrm{mol}^{-1}$ at $0^{\circ} \mathrm{C}$ :

$$
\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightarrow \mathrm{H}_{2} \mathrm{O}(\mathrm{~s}) \quad \Delta H_{\mathrm{fus}}=-6.0 \mathrm{~kJ} \mathrm{~mol}^{-1}
$$

The enthalpy of fusion and the melting point of a crystalline solid depend on the strength of the attractive forces between the repeating units present in the crystal. Molecules with weak attractive forces form crystals with low melting points while crystals consisting of particles with stronger attractive forces melt at higher temperatures.

## Sublimation and deposition

Some solids can undergo transition directly into the gaseous state, bypassing the liquid state, via a process known as sublimation. For example, at room temperature and standard pressure, a piece of dry ice (solid $\mathrm{CO}_{2}$ ) use in fire extingushers sublimes (disappear) without ever forming any liquid. Snow and ice sublime at temperatures below the melting
point of water. When solid iodine is warmed, the solid sublimes and a vivid purple vapor forms. The reverse of sublimation is called deposition, a process in which gaseous substances condense directly into the solid state, bypassing the liquid state. The formation of frost is an example of deposition.

Like vapourization, the sublimation requires an input of energy to overcome intermolecular attractions. The enthalpy of sublimation, $\Delta H_{\text {sub }}$, is the energy required to convert one mole of a substance from the solid to the gaseous state. For example, the sublimation of carbon dioxide is represented by:

$$
\mathrm{CO}_{2}(\mathrm{~s}) \rightarrow \mathrm{CO}_{2}(\mathrm{~g}) \quad \Delta H_{\text {sub }}=26.1 \mathrm{~kJ} \mathrm{~mol}^{-1}
$$

Likewise, the enthalpy change for the reverse process of deposition is equal in magnitude but opposite in sign to that for sublimation:

$$
\mathrm{CO}_{2}(\mathrm{~g}) \rightarrow \mathrm{CO}_{2}(\mathrm{~s}) \quad \Delta \mathrm{H}_{\mathrm{sub}}=-26.1 \mathrm{~kJ} \mathrm{~mol}^{-1}
$$

Consider the extent to which intermolecular attractions must be overcome to achieve a given phase transition. Converting a solid into a liquid requires that these attractions be only partially overcome; transition to the gaseous state requires that they be completely overcome. As a result, the enthalpy of fusion for a substance is less than its enthalpy of vapourization. This same logic can be used to derive an approximate relation between the enthalpies of all phase changes for a given substance. Though not an entirely accurate description, sublimation may be conveniently modeled as a sequential two-step process of melting followed by vapourization for which Hess Law can be applied.

$$
\text { solid } \rightarrow \text { liquid: } \quad \Delta H_{\text {fus }} \text { and liquid } \rightarrow \text { gas: } \quad \Delta H_{\text {vap }}
$$

Therefore by applying Hess's law we can write,

$$
\text { solid } \rightarrow \text { gas: } \quad \Delta H_{\text {sub }}=\Delta H_{\text {fus }}+\Delta H_{\text {vap }}
$$

Viewed in this manner, the enthalpy of sublimation for a substance may be approximated as the sum of its enthalpies of fusion and vaporization, as illustrated in Figure 2.37.

Figure 2.37 For a given substance, the sum of its enthalpy of fusion and enthalpy of vapourization is approximately equal to its enthalpy of sublimation.

The processes of phase transiations described above can be experimentally observed by constructing either heating or cooling curves. When a substance for example ice $\left(\mathrm{H}_{2} \mathrm{O}(\mathrm{s})\right)$
being heated or cooled reaches a temperature corresponding to one of its phase transitions (melting/fusion) and further heating results in vapourization. The heating curve of this process is depicted in the Figure 2.38.

Figure 2.38 A typical heating curve for water depicts changes in temperature that result as the substance absorbs increasing amounts of heat. Plateaus in the curve (regions of constant temperature) are exhibited when the water undergoes phase transitions. Longer plateau for the equilibrium of $\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{H}_{2} \mathrm{O}(\mathrm{g})$ compared to that of $\mathrm{H}_{2} \mathrm{O}(\mathrm{s}) \rightleftharpoons \mathrm{H}_{2} \mathrm{O}(\mathrm{l})$ is due to $\Delta H_{\text {fus }}<\Delta H_{\text {vap }}$.

## Example 2.45

How much heat is required to convert 180 g of ice at $-15^{\circ} \mathrm{C}$ into liquid water at $0^{\circ} \mathrm{C}$ ?

## Answer

First, 180 g ( 10 moles ) of ice at $-15^{\circ} \mathrm{C}$ has to be converted into ice at $0^{\circ} \mathrm{C}$. The heat required for this can be calculated by using $q_{1}=m s(\Delta t)$, where, $s$ is the specific heat capacity of ice: $2.09 \mathrm{~J} \mathrm{~g}^{-1}{ }^{\circ} \mathrm{C}^{-1}$

$$
\therefore q_{1}=m s(\Delta t)=180 \mathrm{~g} \times 2.09 \mathrm{~J} \mathrm{~g}^{-1}{ }^{\circ} \mathrm{C}^{-1} \times 15^{\circ} \mathrm{C}=5643 \mathrm{~J}=5.6 \mathrm{~kJ}
$$

Then, the heat needed to induce a phase change of ice to liquid water is a given $q_{2}=n \times \Delta H_{f u s}$.

$$
\therefore q_{2}=10 \mathrm{~mol} \times 6.0 \mathrm{~kJ} \mathrm{~mol}^{-1}=60 \mathrm{~kJ}
$$

$\therefore$ Total heat required $=q_{1}+q_{2}=65.6 \mathrm{~kJ}$

### 2.5.6 Phase diagrams of pure substances

As we know, a phase is simply a physical state of a substance present under given conditions such as at a given temperature and pressure. That is, a phase is another meaning for solid, liquid or gas. If we consider some ice floating in water, there are two phases of a solid present and a liquid. If there is air above the mixture, then that is another phase.

We can further understand this by considering the system where oil floats on water. This consists two phases of liquids, oil and water. If the oil and water are contained in a beaker, then beaker is yet another phase. From this we can recognise the presence of the different phases and they are separated by a boundary between them.

## Phase diagrams

A phase diagram depicts exactly what phases are present at any given temperature and pressure and they are separated by lines which are called boundaries between them. The line between two phases gives the temperature and pressure at which two phase are in equilibrium. For simplicity of understanding first we will consider phase diagrams of pure substances or we define these as phase diagrams of one-component systems. For example, Figure 2.39 shows a skeptual phase diagram of a one component system.

In the diagram we can see that there are three lines, three areas marked "solid", "liquid" and "vapour", and two special points marked "C" and "T". This indicates that we have a pure substance at three different sets of conditions of ranges of temperature and pressure corresponding to solid, liquid and vapour phases.

Figure 2.39 Phase diagrams of one component system. In (a) curve TB represents the equilibrium that can exist between the molecules of a given solid and those of the same compound in its liquid state. This situation is only found at the melting point of the compound concerned. Line TB is therefore represents the melting point at various pressures. The line TC represents the equilibrium that exists between molecules in the vapour phase and those in the liquid state, i.e. the equilibrium that is found at the boiling point of the compound concerned. The line TC then shows the variation of boiling point with pressure. AT represents the sublimation curve showing the relationship that exists between the sublimation temperature and the pressure - an equilibrium which is only possible if the external pressure is below that at T , the triple point of the compound. (b) shows the equilibria existing in those regions and the signs of $\Delta S$ and $\Delta H$.

## Point T: The triple point

In the phase diagram shown in Figure 2.39, the three curves representing solid-vapour equilibrium (curve AT), solid-liquid equilibrium (curve TB ) and liquid-vapour equilibrium (curve TC) meet at the point T .

Where all three curves meet, there is a unique combination of temperature and pressure where all three phases are in equilibrium together and that point is called the triple point. If the conditions of temperature and pressure are controlled in order to reach this point, there would be an equilibrium which involves the solid melting and subliming, and the boiling liquid in contact with its vapour.

## Point C : Critical point

In the phase digram illustrated in Figure 2.39, the liquid-vapour equilibrium curve (TC) has a top limit labelled $\mathbf{C}$. This is known as the critical point. The temperature and pressure corresponding to this are known as the critical temperature (Tc) and critical pressure.

If the pressure of a gas is increased at a temperature lower than the critical temperature, the system will cross the liquid-vapour equilibrium line and the vapour will condense to give a liquid. However, when the temperature is above the critical temperature, thre is no any line to cross. That is because, above the critical temperature, it is impossible to condense/liquify a gas into a liquid just by increasing the pressure. What we get only is a highly compressed gas.

For example, if the gaseous molecules are compressed together by a high external pressure, but with a temperature high enough not to allow condensation to occur, we will have properties pertaining to both the liquid as well as the gaseous states. The density will be that of a liquid but in this state called the super critical fluid state, the compound behaves like a gas also.

The critical temperature obviously varies from substance to substance and depends on the strength of the attractions among molecules. "The stronger the intermolecular attractions, the higher the critical temperature."

Understanding of the bevaviour of the substance undergoing phase changes can be interpreted as follows with the help of Figure 2.40.

## Point P: Solid phase

In the Figure 2.40 (a), we can see that at the point $\mathbf{I}$ with temperature $\left(\mathrm{T}_{1}\right)$ and pressure $\left(\mathrm{P}_{1}\right)$ water exists as a solid. Assume that the temperature of the system is slowly increased to $\left(\mathrm{T}_{2}\right)$ while keeping the pressure constant $\left(\mathrm{P}_{1}\right)$, i.e. temperature moves along the line $P Q$. It crosses the curve TB at the point X at which there is equilibrium between solid and
liquid (Anywhere on this line, there is an equilibrium between solid and liquid.) and then turn to a pure liquid at the temperature $\mathrm{T}_{2}$ (point Q ) or in other words, it melts.

If we repeate this at a higher fixed pressure $\left(\mathrm{P}_{2}\right)$, the melting temperature is higher $\left(\mathrm{T}^{\prime}\right)_{2}$. See the point I` as illustrated in Figure 2.40 (a). From this we can understand that the curve TB which separate solid and liquid phases simply illustrates the effect of pressure on melting point of a solid.

Further understanding of this behaviour of change in melting point can be treated as follows: As now you have knowledge on Le Chatelier's principle, increase in the pressure leads the equilibrium to move in such a way as to counter the change. As we are having solid $\rightleftharpoons$ liquid equilibrium, increasing the pressure on the equilibrium mixture of solid and liquid at its original melting point will convert the mixture back into the solid again. In other words, it will no longer melt at this temperature. Therefore, to make it melt at this higher pressure $\left(\mathrm{P}_{2}\right)$, increase in the temperature is needed. Thus, raising the pressure raises the melting point of most solids.

## Point Q

If we continue heating at the same pressure $\left(\mathrm{P}_{1}\right)$, along line PR , the liquid will meet the TC curve at point Y at which there is equilibrium between liquid and vapour and then turns into a pure vapour at the temperature $\mathrm{T}_{3}$ (point R ). In other words, it vapourizes. i.e., the liquid will change into a vapour through boiling when it crosses the boundary line between the two phases (TC curve) shown in Figure 2.40 (b). Therefore by varying the temperature at a constant pressure the boiling temperature can easily be read at that pressure from the phase diagram. As we know, anywhere along this line, there will be an equilibrium between the liquid and the vapour.

Further, if the pressure of the system is decreased by keeping the temperature constant at $\mathrm{T}_{2}$, (downward arrow from "point Q"), we meet the TC curve and further decrease in pressure to $\mathbf{P}_{2}$ ` will turn the liquid into vapour. Therefore, the curve TC illustrates the effect of pressure on the boiling point of the liquid. As the pressure increases, the boiling point increases and vice versa.

## Point S: Moving from solid to vapour

Consider the point $\mathbf{S}$ labelled in the phase diagram in Figure 2.40 (c). Solid phase exists at that given temperature $\left(\mathrm{T}_{4}\right)$ and pressure $\left(\mathrm{P}_{4}\right)$. The curve AT represents the boundary between solid and vapour phases on which solid-vapour equilibrium exists. As we have discussed the points P and Q , the curve AT can be crossed by either increasing the temperature of the solid, or decreasing the pressure.

The arrow in the diagram shows the effect of increasing the temperature of a solid phase at a (probably very low) constant pressure. The pressure obviously has to be low enough that a liquid can't form - in other words, it has to happen below the point labelled $\mathbf{T}$. Once
the line meets the curve AT, solid starts to sublime attaining equilibrium between solid and vapour phases. When the selected temperatures and pressures are below the temperature and pressure of the point $\mathbf{T}$ we can see that only the solid or vapour phase can exists in the system. Once the point T is passed, it can be seen that the vapour at a constant temperature can be converted into a liquid by increasing the pressure, where the phenomenon of liquifaction of gasses can be understood.

Figure 2.40 Behaviour of substance undergoing phase changes

## Normal melting and boiling points

As the normal melting and boiling points are the temperatures when the pressure is 100 kPa , these can be found from the phase diagram by drawing a line across 100 kPa pressure.

## Deatailed phase diagram of water

Notice that the triple point for water occurs at a very low pressure of 611 Pa and at the temperature of $0.01{ }^{\circ} \mathrm{C}$. Melting and boiling points are at $0.00{ }^{\circ} \mathrm{C}$ and $100{ }^{\circ} \mathrm{C}$, respectively, where the pressure is 100 kPa . The critical temperature is $374{ }^{\circ} \mathrm{C}$ and the critical pressure is 201 kPa . The complete phase diagram of water is thus depicted in the Figure 2.41 with the inclusion of above information.

Note: In the case of water, "the melting point gets lower at higher pressures".
For the melting, we have the equilibrium of;

$$
\text { Ice } \rightleftharpoons \text { Water }
$$

Ice is less dense than water; therefore, water formed by melting of ice occupies a smaller volume. When the pressure is increased, according to Le Chatelier's Principle the equilibrium will move to reduce the pressure again. That means it will move to the side with the smaller volume. Liquid water is produced. Therefore, to make the liquid water freeze again at this higher pressure, temperature has to be reduced and hence higher pressures bring about lower melting (freezing) points. Thus, the slope of the line/curve for the equilibrium between solid and liquid phases of water has a negative gradient.

## G.C.E. (A/L) CHEMISTRY: UNIT 12 Chemical Equilibrium

Figure 2.41 Phase diagram of water
When the different phases of water are considered there is a marked difference in the density near ambient conditions and at critical conditions. For example:
At $100 \mathrm{kPa}(1 \mathrm{~atm})$ and $0^{\circ} \mathrm{C}$ :
Density of liquid water $=1 \mathrm{~g} \mathrm{~cm}^{-3}=55.6 \mathrm{~mol} \mathrm{dm}^{-3}$
Density of gaseous water $=2.7 \times 10^{-4} \mathrm{~mol} \mathrm{dm}^{-3}$

At 218 atm and $374^{\circ} \mathrm{C}$ :
Density of gaseous water $=$ Density of liquid water $=4.1 \mathrm{~mol} \mathrm{dm}^{-3}$

Phase diagram of $\mathrm{CO}_{2}$ is shown in the Figure 2.42.

Figure 2.42 Phase diagram of $\mathrm{CO}_{2}$
Compared to the phase diagram of water, the only thing special about the the phase diagram of $\mathrm{CO}_{2}$ is the position of the triple point which is well above atmospheric pressure. Therefore, it is impossible to get any liquid carbon dioxide at pressures less than 5.11 atm . That is $\mathrm{CO}_{2}$ does not display normal melting and boiling points. That means at 1 atm pressure, carbon dioxide can only sublime at a temperature of $-78^{\circ} \mathrm{C}$. This is the reason why solid carbon dioxide is often known as "dry ice". You can't get liquid carbon dioxide under normal conditions - only the solid or the vapour.

### 2.6 Liquid - vapour equilibrium in binary liquid systems

In this section, characteristics of the mixtures of two volatile liquids will be discussed wth the help of therotical concepts first. In the first part the discussion is made on the cases where the two liquids are entirely miscible in all proportions to give a single liquid. To understand the behaviour of these solutions, a concpt of an ideal mixture will be introduced and the characteristics of phase diagrams of such ideal mixtures. Are dealt with. Later on, a comparison between ideal and non-ideal mixtures will be made.

### 2.6.1 Characteristics of ideal mixtures

When a completly miscible liquid mixture is formed by mixing two very closely similar liquids, we assume that they get fairly close to being ideal. Some examples are hexane and heptane, benzene and toluene, water and ethanol etc.

## Intermolecular forces

As we have discuused under the vapour pressure, in a pure liquid, some of the more energetic molecules have a tendency to escape from the liquid surface to form the vapour and in substances having smaller intermolecular forces, more molecules will be able to escape at any given temperature. For another liquid the same thing is true and this is illustrated in Figure 2.43.

Figure 2.43 Formation of 1:1 ideal liquid mixture $A B$ with the pure components of $A$ and $B$
Once these two liquids are mixed assuming a complete miscibility the resultant mixture is said to be an ideal (subjected to obey some rules), and the tendency of the two different molecules of the liquids to escape is unchanged as described in Figure 2.43(c).

In the Figure 2.43(c) you can see that when the mixture is $1: 1$ of the two liquids and the proportion of each type of molecule escaping is the same. In other words, the number of molecules escape from each component of the mixture is the same.

If A and B molecules still have the same tendency to escape as before (when they exist alone), we can understand that the intermolecular forces between two A molecules must be exactly the same as the intermolecular forces between a A and a B molecule (If the forces were any different, the tendency to escape would change).

With this characteristic we can understand that the intermolecular interactions between A and B molecules also be exactly the same as the interactions between A-A and B-B molecules.

## Enthalpy change of mixing

When a mixture of liquids is made, breaking of the existing intermolecular attractions and the remaking of new attarctions occur. Energy is needed to break the interactions while energy is released during the formation of new attarctions. If all these attractions are the same, there won't be any heat either evolved or absorbed. That means an ideal mixture of two liquids will have zero enthalpy change of mixing.

> At a given temperature, when a binary completely miscible liquid mixture is formed by mixing liquid $A$ and liquid $B$, with the intermolecular interactions between $f_{A-A}, f_{B-B}$ and $f_{A-B}$ are equal $\left(f_{A-A}=f_{B-B}=f_{A-B}\right)$ and with no enthalpy change, such a solution is called an ideal solution.

A mixture of hexane and heptane gets close to ideal behaviour because they are similar in size and so have equal van der Waals attractions between them.

## Roult law

Consider and ideal binary liquid solution (mixture) made by mixing of liquids $\mathbf{A}$ and $\mathbf{B}$ in a closed container with a vaccum above at a given temperature. As we know, the molecules of $\mathbf{A}$ and $\mathbf{B}$ with sufficient energy will escape into the space above the surface of liquid and build up a pressure. Once the system reaches the dynamic equilibrium, rates of evaporation and condensation of $\mathbf{A}$ and $\mathbf{B}$ become equal. The dynamic equilibrium at this pont can be testified with the consistency of the total vapour pressure and the composition of the vapour phase at a constant temperature. According to Dolton law, total pressure is the sum of partial pressures of components in the system. Composition of the vapour phase depends on the relative volatilities (boiling points) of $\mathbf{A}$ and $\mathbf{B}$ and the relative concentrations of $\mathbf{A}$ and $\mathbf{B}$ in the solution.

The component with high volatility (low boiling point) and higher concentration in solution tends to buid up the higher partial pressure. That is, concentration of a component in the vapour phase is proportional to its partial pressure $\left([\mathrm{A}(\mathrm{g})] \alpha p_{\mathrm{A}}\right)$ and in a mixture the concentration of a component is proportional to its mole fraction ([ $\mathrm{A}(1)] \alpha$ $\left.x_{\mathrm{A}}\right)$.

Consider the vapor - liquid equilibrium of an ideal solution with components $\mathbf{A}$ and $\mathbf{B}$ described above. As the rate of evaporation equals the rate of condensation, we can write:

## G.C.E. (A/L) CHEMISTRY: UNIT 12 Chemical Equilibrium

$$
\begin{equation*}
\mathrm{A}(\mathrm{l}) \stackrel{r_{v}}{\stackrel{\rightleftharpoons}{\rightleftharpoons}} \mathrm{r} \mathrm{r}_{c}(\mathrm{~g}) \quad \ldots \ldots .(1) \quad \mathrm{B}(\mathrm{l}) \underset{r_{c}^{\prime}}{\stackrel{r_{v}^{\prime}}{\rightleftharpoons}} \mathrm{B}(\mathrm{~g}) \tag{1}
\end{equation*}
$$

$r_{v}$ and $r_{c}$ are the rates of vapourization and condensation, respectively of the component A.
$r_{v}^{\prime}$ and $r_{c}^{\prime}$ are the rates of vapourization and condensation, respectively of the component $B$.

Considering (1), we can write;

$$
r_{v}=k[\mathrm{~A}(\mathrm{l})]=k_{1} x_{\mathrm{A}}
$$

$X_{A}$ is the mole fraction of A in solution.
Likewise,

$$
r_{v}^{\prime}=k^{\prime}[\mathrm{A}(\mathrm{~g})]=k_{2} p_{\mathrm{A}}
$$

$P_{A}$ is the partial pressure of A in vapour phase.
At equilibrium,

$$
\begin{gathered}
r_{v}=r_{v}^{\prime} \\
k_{2} p_{\mathrm{A}}=k_{1} x_{\mathrm{A}} \\
\therefore p_{\mathrm{A}}=\frac{k_{1}}{k_{2}} x_{\mathrm{A}} \text { or } \therefore p_{\mathrm{A}}=k x_{\mathrm{A}} \\
\text { when } x_{\mathrm{A}}=1, p_{\mathrm{A}}=p_{\mathrm{A}}^{0}=\text { saturated vapor pressure of } A \\
\therefore k=p_{\mathrm{A}}^{0} \\
\therefore \quad p_{\mathrm{A}}=p_{\mathrm{A}}^{0} x_{\mathrm{A}} \\
\text { and } p_{\mathrm{B}}=p_{\mathrm{B}}^{0} x_{\mathrm{B}}
\end{gathered}
$$

Thus;
In an ideal solution, the partial pressure of a given component is equal to the product of its saturated vapour pressure and the mole fraction of it in the liquid phase at a constant temperature. This relationship is called Roult law.

It is clear that $\therefore \quad p_{\mathrm{A}}<p_{\mathrm{A}}^{0}$ and $p_{\mathrm{B}}<p_{\mathrm{B}}^{0}$
Therefore, decrease or lowering in the vapor pressure of A
$=p_{A}^{0}-p_{\mathrm{A}}=p_{\mathrm{A}}^{0}-p_{\mathrm{A}}^{0} x_{\mathrm{A}}=p_{\mathrm{A}}^{0}\left(1-x_{\mathrm{A}}\right)$
$=p_{\mathrm{A}}^{0} x_{\mathrm{B}}$

$$
\therefore \frac{p_{\mathrm{A}}^{0}-p_{\mathrm{A}}}{p_{\mathrm{A}}^{0}}=x_{\mathrm{B}} \text { and } \frac{p_{\mathrm{B}}^{0}-p_{\mathrm{B}}}{p_{\mathrm{B}}^{0}}=x_{\mathrm{A}}
$$

The above is an alternative form of Roult law.
Relative lowering of vapour pressure of a given component in the vapour phase is equal to the mole fraction of the other component in the solution.

Combining the Roult law with Dolton law of partial pressures, it is possible to determine the composition in the vapour phase. If $\boldsymbol{p}$ is the total vapour pressure and $\boldsymbol{y}_{\mathrm{A}}$ and $\boldsymbol{y}_{\mathrm{B}}$ are the mole fractions of A and B in the vapor phase, respectively, from Dolton law:
$p_{\mathrm{A}}=p y_{\mathrm{A}}=\left(p_{\mathrm{A}}+p_{\mathrm{B}}\right) y_{\mathrm{A}}$

$$
\begin{gathered}
p_{\mathrm{A}}^{0} x_{\mathrm{A}}=\left(p_{\mathrm{A}}^{0} x_{\mathrm{A}}+p_{\mathrm{B}}^{0} x_{\mathrm{B}}\right) y_{\mathrm{A}} \\
\therefore Y_{A}=\frac{p_{\mathrm{A}}^{0} x_{\mathrm{A}}}{\left(p_{\mathrm{A}}^{0} x_{\mathrm{A}}+p_{\mathrm{B}}^{0} x_{\mathrm{B}}\right)} \text { and } y_{\mathrm{B}}=\frac{p_{\mathrm{B}}^{0} x_{\mathrm{B}}}{\left(p_{\mathrm{A}}^{0} x_{\mathrm{A}}+p_{\mathrm{B}}^{0} x_{\mathrm{B}}\right)}
\end{gathered}
$$

Roult law is only applied for ideal mixtures or ideal mixtures follow Roult law.

## Vapour pressure/ composition diagrams

In an ideal mixture of two liquids $A$ and $B$, each of $A$ and $B$ is making its own contribution to the overall vapour pressure of the mixture at a constant temperature. When we consider the component A alone we have $p_{\mathrm{A}}=p_{\mathrm{A}}^{0} x_{A} ; p_{\mathrm{A}}^{0}$ being a constant, results a straight line for the dependence of $p_{\mathrm{A}}$ on $x_{\mathrm{A}}$ as shown in Figure 2.44 (a). (if $x=0, p_{\mathrm{A}}=0$. $p_{\mathrm{A}}$ increases proportionately with the increase in $x_{\mathrm{A}}$ : if you double the $x_{\mathrm{A}}, P_{A}$ will be doubled. Therefore, the straight line goes through the ( 0,0 ) point in the graph). Similar behaviour will be followed by the component B . If we assume that $p_{\mathrm{A}}^{0}>p_{B}^{0}$, i.e A is more volatile than $B$, Figure 2.44 (b) shows the line of variation of vapor pressure of $B$ with its composition $\left(x_{\mathrm{B}}\right)$. The total vapour pressure of the mixture at each composition is therefore the sum of the vapour pressures of $A$ and $B$ at the point concerned. The complete graph of the ideal liquid mixture formed by mixing liquids A and B at a constant temperature is shown in Figure 2.44 (c). The line $p_{\mathrm{T}}\left(p_{\mathrm{AB}}\right)$ shows the variation of total vapour pressure of the system with the composition of A and B.

Figure 2.44 Vapour pressure - composition diagrams for an ideal mixture $A B$ which obeys the Roult law at constant temperature. (a) Variation of vapour pressure of component A; (b) variation of vapour pressure of component B included and (c) variation in total vapour pressure of the mixture.

## Temperature (Boliling point) - composition diagrams

As we have discussed before, if the molecules are escaping easily from the liquid surface at a constant pressure it means that the intermolecular forces are relatively weak and the liquid needs little energy to boil and vapourize.

> Therefore, the liquid with the higher vapour pressure at a particular temperature has the lower boiling point.

Or we can understand the relation between vapour pressure and boiling point (temperature) as follows too.

Liquids boil when their vapour pressures become equal to the external atmospheric pressure. If a liquid has a high vapour pressure at a given temperature, little increase in the temperature is enough to bring the vapour pressure equal to the level of the external atmospheric pressure. On the other hand if the vapour pressure is low, more heat/energy is needed to reach the external pressure.

Therefore, the liquid with the higher vapour pressure at a given temperature has the lower boiling point.

When an ideal mixture is formed by two liquids at the same temperature;
the one with the higher vapour pressure is the one with the lower boiling point.

## Constructing a temperature (boiling point) - composition diagram

First what we have to perform is the conversion of vapour pressure - composition diagram to a temperature (boiling point) - composition diagram at constant (external) pressure. Some may think that the task is an easy one with the thaught of it as simply a reciprocal of the vapour pressure - composition diagram. Though it looks like a correct argument still we have to consider some facts as follows.

In the ideal mixture aforesaid with $p_{\mathrm{A}}^{0}>p_{\mathrm{B}}^{0}$ at constant pressure $T_{\mathrm{b}(\mathrm{A})}<T_{\mathrm{b}(\mathrm{B})}$ where $T_{b}$ is the boiling point ( A has a lower boiling point).

For mixtures of A and B, perhaps you might have expected that their boiling points would form a straight line joining the two points. However, it is a curve. You may recall that the vapour pressure of a liquid has an exponential variation with the temperature as discussed in the section 2.5.3 (see the Figure 12.34).

Figure 2.45 Boiling point (temperature) - composition diagrams for an ideal mixture AB at constant pressure. (a) Boiling points of components A and $B$; (b) variation of boiling point of the mixture.

First we can mark the boiling points on the respective axes with $T_{\mathrm{b}(\mathrm{A})}<T_{\mathrm{b}(\mathrm{B})}$ as shown in Figure 2.45 (a) and with the idea on the variation of the vapour pressure of the mixture with the composition of the liquid, the two points can be connected as shown in Figure 2.45 (b).

Now we need to know how the vapour pressure changes with the composition of the vapour. When a liquid mixture is boiled at constant pressure, the more volatile substance escapes to form the vapour more easily than the less volatile one. That means, in the present system higher proportion of A (the more volatile component) will be in the vapour than in the liquid. The composition of the vapour at this point can be estimated /determined by condensing the vapour first and analyzing it. Consider the point ( P ) marked on the diagram as shown in Figure 2.46 (a). The liquid at point P boils at temperature $T_{p}$ and the composition of the vapour corresponding to $T_{p}$ can be obtained by drawing a horizontal line through P and $\mathrm{T}_{\mathrm{p}}$. That the point in vapour is marked as Q .

Repeating this exercise with liquid mixtures with different compositions of the liquid, the second curve for the variation of the vapour pressure of the vapour with the composition can be plotted as shown in Figure 2.46 (b). We can see that the area inside the two lines consists of an equilibrium between the liquid and the vapour.

Figure 2.46 Boiling point (temperature) - composition diagrams for an ideal mixture AB at constant pressure. (a) Variation of boiling point of the mixture with the selected liquid composition $\mathrm{C}_{1}$ which boils at $\mathrm{T}_{\mathrm{p}}$. Extrapolation of the line $\mathrm{T}_{\mathrm{p}} \mathrm{P}$ gives the composition of vapour at point $P$. (b) Variation of the boiling point in the vapor and inside envelop where the equilibrium liquid $\rightleftharpoons$ vapor exists. (c) Finds the composition of the liquid corresponds to the point Q as $\mathrm{C}_{2}$.

As described in Figure 2.46 (b), by boiling a liquid mixture we can find the temperature at which it boils, and the composition of the vapour over the boiling liquid. For example, in the Figure 2.46 (c), a liquid mixture of composition $\mathrm{C}_{1}$ boils at a temperature $\mathrm{T}_{1}$ and the vapour over the top of the boiling liquid will have the composition $\mathrm{C}_{2}$. Likewise we can repeat this for other compositions and from the liquid composition curve the boling point can be determind. Then the composition of the vapour in equilibrium with the liquid of that composition could be estimated. This behaviour is very helpful in separating liquids from mixtures through distillation/ fractional distillation and the details on this will be discussed in a later section. Before going to discus that application it is worth seeing the characteristics of systems of liquid mixtures showing some devistions from the Roult law.

## Non-ideal mixtures of liquids

A liquid mixture which does not obey Roult law is called a non-ideal liquid mixture. Such a mixture is formed by the components A and B among which the intermolecular interactions are not equal. These systems differ in behavior from ideal mixtures. In a nonidael mixture with components A and $\mathrm{B}, f_{A-A} \neq f_{B-B} \neq f_{A-B}$, so there is a change in enthalpy during mixing. Therefore, the tendency for the molecules to escape is not the same in the mixture and in the pure liquids.

## Vapour pressure - composition diagrams for non-ideal mixtures

As we know, the ideal mixtures obey the Roult law and dependence of vapour pressure on the composition of the liquid phase at a constant temperature results in a straight line as shown in Figure 2.44 (a), where A is the more volatile one and hence $p_{\mathrm{A}}^{0}>p_{\mathrm{B}}^{0}$.

Figure 2.47 Vapour pressure - composition diagrams for non-ideal mixture AB at constant temperature. (a) Positive deviation from Roult law and (b) negative deviation from Roult law. (c) Shows mixtures having large positive and negative deviations from Roult law.

## Positive deviations from Raoult law

Some mixtures are formed at constant temperature by components A and B where $f_{A-B}<f_{A-A}$ and $f_{B-B}$, i.e. the intermolecular forces between molecules of A and B are less than those in pure liquids. Therefore, the tendency for the molecules to escape into the vapour phase is higher than that in the case of an ideal mixture.
Therefore, $p_{\mathrm{A}}>p_{\mathrm{A}}^{0} x_{\mathrm{A}}$ and $p_{\mathrm{B}}>p_{\mathrm{B}}^{0} x_{\mathrm{B}}$ : this results;

$$
p_{\mathrm{AB}}>\left(p_{\mathrm{A}}^{0} x_{\mathrm{A}}+p_{B}^{0} x_{\mathrm{B}}\right)
$$

This means that the total vapor pressure of the mixture is higher than that of an ideal mixture;

$$
p_{\mathrm{AB}}>p_{(\mathrm{AB})_{\text {ideal }}}
$$

These type of mixtures/solutions are said to exhibit positive deviations from Roult law. In mixtures showing a positive deviation from Raoult's Law, the vapour pressure of the mixture is always higher than that expected from an ideal mixture. Thus, the curve in the vapour pressure - composition diagram loops upwards from the ideal line as shown in Figure 2.47 (a). In these mixtures, the vapour pressure which is higher than that of ideal mixtures implies that molecules are breaking away more easily than they do in the pure liquids. As the intermolecular forces between molecules of A and B are less than they are in the pure liquids, less heat is evolved than the heat absorbed to break the original attractions between molecules A-A and B-B when the liquids are mixed. Heat will therefore be absorbed when these liquids are mixed. Thus, the enthalpy change of mixing is positive (endothermic). We can see that along this curve the highest vapour pressure anywhere is still the vapour pressure of pure A as $p_{\mathrm{A}}^{0}>p_{\mathrm{B}}^{0}$. Cases like this, where the deviation is small, behave just like ideal mixtures as far as distillation is concerned. But some liquid mixtures have very large positive deviations from Raoult law and in these cases, the curve becomes distorted as shown in Figure 2.47 (c). For example a mixture of
this kind is ethanol and water that produces a highly distorted curve with a maximum vapour pressure for a mixture containing $95.6 \%$ of ethanol by mass.

## Negative deviations from Raoult's law

In some mixtures formed at constant temperature by components A and B with $f_{A-B}>f_{A-A}$ and $f_{B-B}$, the tendency for the molecules to escape into the vapour phase is less than that in the case of an ideal mixture. That is the molecules break away from the mixture less easily than they do from the pure liquids. Thus stronger forces must exist in the mixture than in the original liquids.
Therefore, $p_{\mathrm{A}}<p_{\mathrm{A}}^{0} x_{\mathrm{A}}$ and $p_{\mathrm{B}}<p_{\mathrm{B}}^{0} x_{\mathrm{B}}$ : this results;

$$
p_{\mathrm{AB}}<\left(p_{\mathrm{A}}^{0} x_{\mathrm{A}}+p_{\mathrm{B}}^{0} x_{\mathrm{B}}\right)
$$

This means that the total vapor pressure of the mixture is lower than that of an ideal mixture;

$$
p_{\mathrm{AB}}<p_{(\mathrm{AB})_{\text {ideal }}}
$$

These type of mixtures/solutions are said to exhibit negative deviations from Roult law. In mixtures showing a negative deviation from Raoult's Law, the vapor pressure of the mixture is always lower than that expected from an ideal mixture. Thus, the curve in the vapour pressure - composition diagram loops downwards from the ideal line as shown in Figure 2.47 (b). We can see a minimum and along this curve the highest vapour pressure anywhere is still the vapour pressure of pure A as $p_{\mathrm{A}}^{0}>p_{\mathrm{B}}^{0}$. On mixing the liquids to form this type of a mixture, heat is evolved because the new bonds formed are stronger than the original weaker ones which are broken. For example when water and nitric acid is mixd, more heat is evolved because of the formation of ionic species $\mathrm{NO}_{3}^{-}$and $\mathrm{H}_{3} \mathrm{O}^{+}$ (Figure 2.47 (c)).

## Boiling point - composition diagrams for non-ideal mixtures

A mixture with positive deviation from Roult law has a high vapour pressure which means that it has a low boiling point. The molecules escape easily and it is not necessary to heat the mixture much to overcome the intermolecular attractions completely. Therefore, the boiling point - composition curve will have a minimum value lower than the boiling points of either A or B as shown in Figure 2.48 (a). For example, in the mixture of ethanol and water, this minimum occurs with $95.6 \%$ of ethanol by mass in the mixture. The boiling point of this mixture is $78.2^{\circ} \mathrm{C}$ where as the boiling point of pure ethanol is $78.5^{\circ} \mathrm{C}$, and the boiling point of water is $100^{\circ} \mathrm{C}$.

(a)

(b)

Figure 2.48 Boiling point - composition diagrams for non-ideal mixture AB at constant temperature. (a) Positive deviation from Roult law and (b) negative deviation from Roult law.

In the case of the mixtures with negative deviation from Roult law, molecules break away to form the vapour with much more difficulty than in either of the pure liquids. Therefore, such mixtures can have boiling points higher than either of the pure liquids because it needs extra heat to break the stronger forces in the mixture. Therefore, the variation of boiling point with the composition goes through a maximum value compared to boiling points of pure A and B and is shown in Figure 2.48 (b). For example, in a mixture of nitric acid and water, there is a maximum boiling point of $120.5^{\circ} \mathrm{C}$ when the mixture contains $68 \%$ by mass of nitric acid. That can be compared with the boiling point of pure nitric acid $\left(86{ }^{\circ} \mathrm{C}\right)$, and water $\left(100^{\circ} \mathrm{C}\right)$. It is easy to understand that this large difference in boiling points is due to the presence of the new ionic interactions as described earlier.

## Fractional distillation

Consider Figure 2.44 (c) and assume that the vapour relavent to the liquid composition $\mathrm{C}_{1}$ is collected and condensed to get a new liquid mixture with the composition $\mathrm{C}_{2}$ which is reboiled. This liquid will boil at a new temperature $\mathrm{T}_{2}$, and the vapour over the top of it would have a composition $\mathrm{C}_{3}$ as shown in Figure 2.49. We can see that the vapour with composition $\mathrm{C}_{3}$ is very close to pure A . Therefore, by repeating this process of condensing the vapour and reboiling the resultant liquid will eventually end up with pure A. This process is the basis of the technique called fractional distillation which is very useful in separating liquid mixtures to their pure components

Figure 2.49 Concept of fractional distillation
If we continue the process of ocondensing and reboiling described in Figure 2.49, reboiling liquid $\mathrm{C}_{3}$ will give a vapour still richer in the more volatile component A and we will be able to collect a liquid which is virtually pure $B$. Therefore, we can notice that the more volatile component from a mixture of liquids can be separated by successive boiling-condensing-reboiling operations. However, the repeating of this process is really time consuming and it needs some high efficiency in the view of industrial applications. Also it is not quite clear how a component with high boiling point is obtained. Fractionating columns are used to overcome this barrier by automating this condensing and reboiling process. Figure 2.50 shows a sketch of a complete set up used for fractional distillation with a fractionating column.

Figure 2.50 A sketch of the complete set up use for the fractional distillation with fractionating column

The fractionating column is packed with glass beads or spikes attached to the walls of a column to facilitate the vapour to condense. These glass beads or spikes make a lot of surface area inside the column allowing the maximum possible contact between the liquid falling down and the hot vapour rising leading to efficient boiling - condensation cycles. A thermometer bulb is placed exactly at the outlet of the fractionating column and the column is connected to a water-cooled condenser.

Consider boiling of a mixture with composition $\mathrm{C}_{1}$.

## Analysing the vapor;

As we know, the vapour over the top of the boiling liquid is richer in the more volatile component with low boiling point, and will have the composition $\mathrm{C}_{2}$ (Figure 2.49). The vapour produced on top of the liquid now starts to travel up along the fractionating column and eventually it will reach a height at which the temperature is low enough to condense it giving a liquid on/in glass beads or spikes. The composition of that liquid is still $\mathrm{C}_{2}$. Once the vapour is condensed, it will start to fall down along the column and will meet new hot vapour rising. Now as the falling liquid mixes up with the hot vapour that will cause it to reboil.

Assume now the composition of the vapour as $\mathrm{C}_{3}$. As described above, this new vapour will again move further up the fractionating column until it gets to a temperature where it can condense. Then the whole process repeats itself. We can see that each time the vapour condenses to a liquid, the liquid will start to fall down the column through the glass beads. It will be reboiled by the up-coming hot vapour producing a vapour rich in the more volatile component A. If the boling points of the two liquids are very close, we need longer fractionating columns.

## Analysing the liquid

As the vapour is richer in the more volatile component A , the liquid remaining in the flask will be getting richer in the other component B . During this repeating process of boilng and condensastions and as the condensed liquid falling down the column constantly reboiled by the up-coming vapour, each reboiling makes it rich in the less volatile component.

Therefore, over the time, component A passes out from the top of the column into the condenser and the liquid in the flask will become richer in B . By controlling the temperature carefully, a binary mixture is separated in which the component A (with lower boling point) passes into the collecting flask and $B$ will remain in the original flask.

### 2.6.2 Immiscible liquid - liquid systems

Immiscible liquids are those which do not mix to give a mixture with a single phase at a given temperature and pressure. Oil and water are examples of immiscible liquids, where oil floats on top of water. Therefore, we can understand that when immiscible liquids are mixed together, they separate out into different layers with the denser liquid settling to
the bottom and the other floating on top of that. In such a case, if the liquids are in a closed container with static condition and there are no interactions between molecules of two liquids, the vapour pressure of the system will simply be the vapour pressure of the one which is floating on top because there is no way for the liquid in the bottom to travel up.

Let us assume that the mixture is stirred or the static situation is perturbed and the two liquids are broken up into drops. Therefore, the top layer of liquid does not alter the bottom layer - molecules to evaporate, though it may slow it down from reaching its equilibrium. Now, at any time there will be drops of both liquids on the surface giving indication that both of them contribute to the overall vapour pressure of the mixture. As such it is desirable to assume that the molecules of both liquids are in equilibrium with their respective molecules in the gas phase and both of those contribute to the total vapour pressure of the system. Therefore, the total vapour pressure of the system would be the sum of partial pressures of the components; assuming that the component liquids are A and B,

$$
p_{\mathrm{T}}=p_{\mathrm{A}}^{\circ}+p_{\mathrm{B}}^{\circ}
$$

Figure 2.51 Variation of vapor pressure of totally immiscible liquid - liquid system

As the two liquids are immiscible, the variation in their vapor pressures with temperature is independent of each other as depicted in Figure 2.51. Once we sum-up these partial pressure values, the total vapour pressure curve intersects the 100 kPa line at a point which has a lower boiling point compared to pure A and B . Therefore, in these types of mixtures of immiscible liquids, it is very important to note that the boiling point of the mixture will be lower than the boling points of the pure components.

This principle is very useful in purification of temperature sensitive compounds, particularly those that decompose at their boiling points. As the mixture boils at a lower temperature than those of the components, it is easy to extract high-boling compounds by the application of steam distillation. For example, phenylamine $\mathrm{C}_{6} \mathrm{H}_{5} \mathrm{NH}_{2}$ oxidizes rapidly at its normal boiling temperature $\left(184{ }^{\circ} \mathrm{C}\right)$. However, a mixture of phenylamine

## G.C.E. (A/L) CHEMISTRY: UNIT 12 Chemical Equilibrium

and water will boil at a temperature lower than $100^{\circ} \mathrm{C}$. With the understanding of the Figure 2.51, we can treat this mixture as follows.

At $98^{\circ} \mathrm{C}$, the saturated vapour pressures of the two pure liquids are:

| phenylamine | 7.07 kPa |
| :--- | :--- |
| water | 94.30 kPa |

The total vapor pressure of the mixture would than be the sum of these which is 101.37 kPa and this is slightly higher than the normal external pressure. Therefore, the mixture would boil at a temperature just less than $98^{\circ} \mathrm{C}$ which is little lower than the boiling point of pure water $\left(100^{\circ} \mathrm{C}\right)$ and much lower than the boiling point of phenylamine $\left(184^{\circ} \mathrm{C}\right)$.

Thus, the isolation of this compound from a mixture can easily be carried out by steam distillation. In this procedure, steam is continuously passed through the heated mixture and the vapour is condensed by a water-cooled condenser. Then the condensed vapour of pure components is collected in a container. It is necessary to keep in mind that the steam distillation technique is useful to separate/purify a substance when the substance is immiscible with water or insoluble in water, has a high molecular mass, has high vapour pressure at around $100^{\circ} \mathrm{C}$ and the impurities present are non volatile under the conditions used.

### 2.7 Partition/ Distribution coefficient

When two immiscible solvents $\mathbf{A}$ and $\mathbf{B}$ are placed in a beaker, they will not mix and instead form separate layers. At a constant temperature, when a solute $\mathbf{X}$ which is soluble in both solvents in the same molecular-form and non-reactive is added, and the system is shook vigorously, the solute X gets dissolved in both solvents depeding on its solubility in each solvent. This can further be explained as the solute is distributed or partitioned between the two solvents. After allowing the system to settle, layers of the solvents will separate and $\mathbf{X}$ molecules of the solute pass through the boundary between two solvents back and forth. Finally a dynamic equilibrium will be reached with the constant concentrations of X in each layer.

Figure 2.52 Skeptual diagram for the distribution of solute X in A and B solvents

## G.C.E. (A/L) CHEMISTRY: UNIT 12 Chemical Equilibrium

At the same temperature, if more of the solute X is added to the system, the solute will distribute itself between the layers keeping the same ratio of the solute concentrations at constant temperature. Therefore, at a constant temperature, the equilibrium constant for the system can be written as:

$$
\frac{\text { Concentration of } \mathrm{X} \text { in } \mathrm{A}}{\text { Concentration of } \mathrm{X} \text { in } \mathrm{B}}=\mathrm{constant}
$$

i.e.

When a solute $X$ distributes itself between two immiscible solvents $A$ and $B$ at constant temperature and $X$ is in the same molecular condition in both solvents,

$$
\frac{\left[\mathrm{X}_{\mathrm{A}}\right]}{\left[\mathrm{X}_{\mathrm{B}}\right]}=K_{\mathrm{D}}
$$

The constant $\boldsymbol{K}_{\mathrm{D}}$ is called the Distribution coefficient or the partition coefficient or the distribution ratio.

When a solute is shaken with two immiscible solvents at a constant temperature, at equilibrium both the solvents are saturated with the solute. Since the solubility also represents concentration, we can write the distribution law as

$$
\frac{\left[\mathrm{X}_{\mathrm{A}}\right]}{\left[\mathrm{X}_{\mathrm{B}}\right]}=\frac{S(\mathrm{X})_{\mathrm{A}}}{S(\mathrm{X})_{\mathrm{B}}}=K_{\mathrm{D}}
$$

$S(\mathrm{X})_{\mathrm{A}}$ and $S(\mathrm{X})_{\mathrm{B}}$ are the solubilities of the solute in the two solvents. Hence knowing the value of the Distribution coefficient $\boldsymbol{K}_{\mathbf{D}}$ and the solubility of solute in one of the solvents, the solubility of solute in the second solvent can be calculated.

## Example 2.46

A solid X is added to a mixture of benzene and water at $25^{\circ} \mathrm{C}$. After shaking well and allowing to settle, $20.00 \mathrm{~cm}^{3}$ of the benzene layer was found to contain 0.20 g of X and $100.00 \mathrm{~cm}^{3}$ of water layer cantained 0.40 g of X . X has its normal molecular weight in both solvents. Calculate the $\boldsymbol{K}_{\boldsymbol{D}}$.

## Answer

Concentration of X in benzene, $C_{\mathrm{b}}=\frac{0.20 \mathrm{~g}}{20.00 \mathrm{~cm}^{3}}=1.0 \times 10^{-2} \mathrm{~g} \mathrm{~cm}^{-3}$
Concentration of X in water, $C_{\mathrm{w}}=\frac{0.40 \mathrm{~g}}{100.00 \mathrm{~cm}^{3}}=4.0 \times 10^{-3} \mathrm{~g} \mathrm{~cm}^{-3}$

$$
\therefore K_{\mathrm{D}}=\frac{C_{\mathrm{b}}}{C_{\mathrm{w}}}=\frac{1.0 \times 10^{-2} \mathrm{~g} \mathrm{~cm}^{-3}}{4.0 \times 10^{-3} \mathrm{~g} \mathrm{~cm}^{-3}}=2.5
$$

Note: It is not necessary to find the concentration in mol dm always. As $K_{D}$ is a dimentionless quantity, units are cancelling out. It is important to remember that the units of both concentrations should be the same.

## Example 2.47

At $25^{\circ} \mathrm{C}$ an aqueous solution of iodine containing $0.05 \mathrm{~g} \mathrm{dm}^{-3}$ is in equilibrium with a carbon tetrachloride $\left(\mathrm{CCl}_{4}\right)$ solution containing $4.00 \mathrm{~g} \mathrm{dm}^{-3}$. The solubility of iodine in water at $25^{\circ} \mathrm{C}$ is $0.40 \mathrm{~g} \mathrm{dm}^{-3}$. Find the solubility of iodine in carbon tetrachloride.

## Answer

$K_{D}=\frac{C_{\mathrm{CCl}_{4}}}{C_{\mathrm{H}_{2} \mathrm{O}}}=\frac{4.00 \mathrm{~g} \mathrm{dm}^{-3}}{0.05 \mathrm{~g} \mathrm{dm}^{-3}}=80$
$\therefore \frac{(\text { Solubility })_{\mathrm{CCl}_{4}}}{(\text { Solubility })_{\mathrm{H}_{2} \mathrm{O}}}=\frac{(\text { Solubility })_{\mathrm{CCl}_{4}}}{0.40 \mathrm{~g} \mathrm{dm}^{-3}}=80$
$\therefore \quad$ (Solubility) $\mathrm{CCl}_{4}=32.00 \mathrm{~g} \mathrm{dm}^{-3}$

## Understanding $\mathbf{K}_{\mathbf{D}}$ as a constant at constant temperature

As we are considering a system in dynamic equilibrium with the distribution of solute X , the rate $\left(r_{1}\right)$ at which molecules of X pass from solvent A to B is proportional to its concentration $\left(C_{1}\right)$ in A . The rate $\left(r_{2}\right)$ at which molecules of X pass from solvent B to A is proportional to its concentration $\left(C_{2}\right)$ in B . At equilibrium, the rate of migration of solute from one solvent to the other is equal at a constant temperature.

Figure 2.53 Distribution of X solute increases to keep the $K_{\mathrm{D}}$ constant at constant temperature

Thus we have,
$r_{1} \alpha C_{1}$ and $r_{2} \alpha C_{2}$
$\therefore r_{1}=k_{1} C_{1}$ and $r_{2}=k_{2} C_{2}$
$k_{1}$ and $k_{2}$ are rate constants.

## G.C.E. (A/L) CHEMISTRY: UNIT 12 Chemical Equilibrium

At equilibrium,
$r_{1}=r_{2} \quad$ therefore, $\quad k_{1} C_{1}=k_{2} C_{2}$

$$
\frac{c_{1}}{c_{2}}=\frac{k_{2}}{k_{1}}=K_{D}
$$

Usually following conditions are necessary to apply this distribution law.
(i) Constant temperature: The temperature should be constant throughout the experiment.
(ii) Same molecular state: The molecular state of the solute should be the same in the two solvents.
(iii)Equilibrium concentrations: The concentrations of the solute are measured or estimated after the equilibrium has been established.
(iv)Dilute solutions: The concentrations of the solute in the two solvents should be low. The law does not hold when the concentrations are high.
(v) Solvents should be immiscibile.

3.4.5 Electrolysis of $\mathrm{NaCl}(1)$ (molten NaCl ) using inert electrodes
3.4.6 Quantitative aspects of electrolysis
3.4.7 Comparison of Galvanic cells and electrolytic cells

## Introduction

Electrochemistry, the study of the exchange between electrical and chemical energy, dealing with chemical reactions that produce electricity in which the energy released by a spontaneous reaction is converted to electricity and/ or electrical energy is used to cause a nonspontaneous reaction to occur. In these specific systems the reactions involve electron transfer, and so they are mainly a pair of reactions named oxidation-reduction (redox) reactions. An oxidation involves the loss of one or more electrons from a chemical species while a reduction involves the gain of one or more electrons by a chemical species. When an oxidation and a reduction are paired together in a redox reaction, electrons can flow from the oxidized species (the reducing agent or reductant) to the reduced species (the oxidizing agent or oxidant). That electron flow can either be spontaneously produced by the reaction and converted into electricity, as in a galvanic cell, or it can be imposed by an outside source to make a non-spontaneous reaction proceed, as in an electrolytic cell. The following descriptions on electrochemistry involve basics in redox reactions, galvanic cells, electrolytic cells, and the applications with electrolysis.

### 3.1 Conductivity

We encounter different materials in our day to day life such as paper, wood, glass, plastics, rubber, metals, and composite materials (i.e. mix of two different kind of materials). These materials have different properties thus differ in applications. One such important property is ability of a material to flow electricity through it. It is necessary to define a few terms before we consider the subject of conductance of electricity through electrolytic solutions. The electrical resistance is represented by the symbol ' $R$ ' and it is measured in ohm $(\Omega)$ which in terms of SI base units is equal to $\left(\mathrm{kg} \mathrm{m}^{2}\right)$. It can be measured with the help of a Wheatstone bridge. The electrical resistance of any object is directly proportional to its length, $l$, and inversely proportional to its area of cross section, $A$. That is,

$$
\begin{array}{ll}
R \propto l & \text { and } R \propto \frac{1}{A} \\
\text { Therefore, } & R \propto \frac{l}{A} \\
& R=\rho \frac{l}{A}
\end{array}
$$

The constant of proportionality, $\boldsymbol{\rho}$ (rho), is called resistivity (specific resistance). Its SI units are ohm metre $(\Omega \mathrm{m})$ and quite often, ohm centimetre $(\Omega \mathrm{cm})$ is also used. That is, physically, the resistivity for a substance is its resistance when it is one metre long and its area of cross section is one $\mathrm{m}^{2}$. It can be seen that: $1 \Omega \mathrm{~m}=100 \Omega \mathrm{~cm}$.

The inverse of resistance, $R$, is called conductance, $G$, and we have the relation,

$$
\text { Conductance }(G)=\frac{1}{R}
$$

The SI unit of conductance is siemens, represented by the symbol ' S ' and is equal to ohm ${ }^{-1}$ (also known as mho) or $\Omega^{-1}$.

Further we can write,

$$
\text { Conductance }(G)=\frac{1}{R}=\frac{A}{\rho l}=\kappa \frac{A}{l}
$$

The inverse of resistivity, $\frac{\mathbf{1}}{\boldsymbol{\rho}}=\boldsymbol{\kappa}$, called conductivity (specific conductance) is represented by the symbol, $\boldsymbol{\kappa}$ (Greek, kappa). The SI units of conductivity are $\mathrm{S} \mathrm{m}^{-1}$ but quite often, $\kappa$ is expressed in $\mathrm{S} \mathrm{cm}^{-1}$. Conductivity of a material in $\mathrm{S} \mathrm{m}^{-1}$ is its conductance when it is 1 m long and its area of cross section is $1 \mathrm{~m}^{2}$. It may be noted that $1 \mathrm{~S} \mathrm{~cm}^{-1}=100 \mathrm{~S} \mathrm{~m}^{-1}$. These definitions can be depicted by Figure 3.1 as given below.

Figure 3.1 Resistance and resistivity
Conductivity and resistivity are constant for a particular substance (metal or an ionic solution with known concentration). However, it is important to provide the temperature at which conductivity or resistivity was measured as it varies with the temperature. In general, about $2 \%$ change in conductivity per one degree Celsius is observed for solutions.

Electricity can be conducted through materials (such as metals) as a flow of electrons in the metal. Such materials are known as electrical conductors. Electricity can also be conducted as a flow of ions in a solution or molten ionic compound. These are called ionic conductors. So, to conduct electricity through materials, it is essential to present electrons (or holes) which can move or ions in solid or liquid state when an electric field is applied.

Solutions can be categorized as strong electrolytes, weak electrolytes and nonelectrolytes (insulators). If a particular substance is fully ionized in solution, such as ionic solids and strong acids/ bases, it is called a strong electrolyte. Such solutions have concentration of ions proportional to the concentration of strong electrolytes used. Examples for strong electrolytes are aqueous solutions of $\mathrm{NaCl}, \mathrm{KNO}_{3}, \mathrm{HCl}$. In the case where electrolytes added are partially ionized in aqueous solution, these are called weak electrolytes. Weak aqueous Bronsted acids and bases such as $\mathrm{CH}_{3} \mathrm{COOH}, \mathrm{NH}_{3}, \mathrm{H}_{2} \mathrm{O}$ are examples for weak electrolytes. The other extreme of electrolytes are the substances
which do not produce ions in aqueous media. These are called non-electrolytes or insulators and these do not conduct electricity. Non polar organic compounds such as Benzene $\left(\mathrm{C}_{6} \mathrm{H}_{6}\right)$ and Kerosene are examples for such non-electrolytes.

The conductivity and resistivity of an electrolyte solution can be measured using two oppositely charged metal electrodes placed in an imaginary cuboid shaped portion of a solution with dimensions, length $(l)$ and area of cross section(A) as shown in Figure 3.2.

Figure 3.2 Conductivity and resistivity through a solution of electrolytes

### 3.1.1 Factors affecting conductivity of a solution

There are several factors which affect the conductivity of a solution. These are: nature of the solute, concentration of the solute, and the temperature of the solution. All of these factors affect conductivity because mobility of charge carriers is dependent on the above factors and as a result conductivity is dependent on the mobility of charge carriers.

The nature of the species plays important role as it determines presence of ions or mobile charge carriers. Aqueous solutions of strong electrolytes (e.g.: $\mathrm{KCl}, \mathrm{NaCl}$ ) can conduct electricity as these species produce ions due to complete dissociation. However, in the solid state these strong electrolytes do not conduct electricity due to absence of ions. If such a solid electrolyte is brought to the molten state, such as $\mathrm{NaCl}(1)$ then ions gain mobility thus conduct electricity. On the other hand, weak acids and bases are also able to conduct electricity as these will react with water to produce ionic species through partial dissociation.

## Example 3.1

Which of the following substances once dissolved in water will conduct electricity?
(a) table salt
(b) glucose
(c) vinegar

## Answer

(a) Chemical formula of table salt is NaCl . It is an electrolyte which fully dissolves in water to produce $\mathrm{Na}^{+}$and $\mathrm{Cl}^{-}$ions. Since table salt is a substance that produces ions in water, it is capable of conducting electricity.
(b) Glucose is an organic compound with formula $\mathrm{C}_{6} \mathrm{H}_{12} \mathrm{O}_{6}$. When glucose is dissolved in water it will not produce any ionic species. Therefore, a glucose solution cannot conduct electricity.
(c) Vinegar is mostly consists of acetic acid, $\mathrm{CH}_{3} \mathrm{COOH}$. Acetic acid is a weak acid which partially dissociates in water to produce $\mathrm{H}_{3} \mathrm{O}^{+}$and $\mathrm{CH}_{3} \mathrm{COO}^{-}$ions. As a result vinegar solution is able to conduct electricity due to presence of ions.

Another important factor that affects the conductivity of a solution is concentration. When the concentration of dilute aqueous solution is decreased, the conductivity is also decreased. This is due to decreased amount and interactions of ions upon dilution. The Table 3.1 illustrates the effect of concentration on conductivity.

Table 3.1 Conductivities of various water samples and solutions at 298 K

| Sample | Conductivity $/ \boldsymbol{\mu S ~ c m}$ |
| :--- | :--- |
| Distilled water | $1-2$ |
| $0.01 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{KCl}$ solution | 1,480 |
| $0.10 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{KCl}$ solution | 12,400 |
| $1.0 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{KCl}$ solution | 110,000 |
| Well water | $100-200$ |
| Pipe borne water | $50-150$ |
| Sea water | 40,000 |
| $\boldsymbol{S}:$ micro seimans |  |

The temperature of the solution has a considerable influence on the conductivity values measured. When the temperature is increased, conductivity of the solution is also increased at a given concentration due to enhanced speed of ions. This effect is clearly demonstrated in the Table 3.2 below.

Table 3.2 Conductivities of $\mathrm{KCl}(\mathrm{aq})$ and solutions at different temperatures

| Concentration $/ \mathbf{m o l ~ d m}^{-3}$ | Conductivity $/ \boldsymbol{\mu S ~ c m}$ |  |  |
| :--- | :--- | :--- | :--- |
|  | $\mathbf{- 1}$ |  |  |
|  | $\mathbf{0} \mathbf{}{ }^{\circ} \mathbf{C}$ | $\mathbf{1 3}{ }^{\mathbf{}} \mathbf{C}$ | $\mathbf{2 5}^{\circ} \mathbf{C}$ |
| 1.00 KCl solution | $6.5 \times 10^{4}$ | $9.8 \times 10^{4}$ | $1.1 \times 10^{5}$ |
| 0.10 KCl solution | $7.2 \times 10^{3}$ | $1.1 \times 10^{4}$ | $1.3 \times 10^{4}$ |
| 0.01 KCl solution | $7.8 \times 10^{2}$ | $1.2 \times 10^{3}$ | $1.4 \times 10^{3}$ |

Current carried by an ion at a given temperature and an electric field depends on the concentration of ions and their speed. The speed of an ion depends on it's charge, size, and potential gradient of the applied electric field. According to Table 3.3, $\mathrm{H}^{+}$and $\mathrm{OH}^{-}$ ions have the highest speeds due to relatively small size. Thus, these ions are major contributors for the conductance of an aqueous solution.

Table 3.3 Speeds of ions in an aqueous solution under the potential gradient $1 \mathrm{~V} \mathrm{~cm}^{-1}$ at 298 K

| Ion | Speed $/ \mathbf{m m}$ min $^{-\mathbf{1}}$ | Ion | Speed $/ \mathbf{m m ~ m i n}{ }^{\mathbf{- 1}}$ |
| :--- | :--- | :--- | :--- |
| $\mathrm{H}^{+}$ | 2.05 | $\mathrm{NO}_{3}{ }^{-}$ | 0.40 |
| $\mathrm{OH}^{-}$ | 1.12 | $\mathrm{Cl}^{-}$ | 0.42 |
| $\mathrm{Na}^{+}$ | 0.29 | $\mathrm{SO}_{4}{ }^{2-}$ | 0.88 |
| $\mathrm{~K}^{+}$ | 0.42 | $\mathrm{Ca}^{2+}$ | 0.67 |

Conductivity of a solution plays an important role when analyzing ionic content of a water sample. In practice, conductivity meters are used to measure the conductivity of a solution. Such measurements can be used in evaluating salinity, calculating solubility products, and in many other applications.

### 3.2 Electrodes in equilibrium

### 3.2.1 Metal - metal ion electrode

Before discussing details about this electrode equilibrium it may be worth understanding the behaviour of reactivity of metals in solutions as that would be the basic concept of building up an electrode.

As we know, when metals react, they give away electrons and form positive ions. For example, $\mathrm{Mg}^{2+}(\mathrm{aq}), \mathrm{Zn}^{2+}(\mathrm{aq})$ or $\mathrm{Cu}^{2+}(\mathrm{aq})$ ions are formed when the respective metals react in aqueous solutions of their ions and form positive and negative charges as shown by the following reaction.

$$
\mathrm{Mg}(\mathrm{~s}) \rightarrow \mathrm{Mg}^{2+}(\mathrm{aq})+2 \mathrm{e}
$$

This occurs as follows; once a piece of solid magnesium is dipped in a beaker of $\mathrm{Mg}^{2+}$ solution there will be some tendency for the magnesium atoms to remove electrons and
go into solution as $\mathrm{Mg}^{2+}(\mathrm{aq})$ ions. The electrons will be left behind on the magnesium as depicted in the Figure 3.3.

Figure 3.3 Behaviour of Mg metal in an aqueous solution of $\mathrm{Mg}^{2+}(\mathrm{aq})$ ions
Once the Mg rod is dipped in $\mathrm{Mg}^{2+}$ solution, there will be a quick build-up of electrons on the magnesium, and it will be surrounded in the solution by a layer of positive $\mathrm{Mg}^{2+}$ ions. These will tend to stay close because they are attracted to the negative charge on the piece of metal. Some of them will be attracted enough that they will reclaim their electrons and stick back on to the piece of metal. A dynamic equilibrium will be established when the rate at which ions are leaving the surface is exactly equal to the rate at which they are joining it again. At that point there will be a constant negative charge on the magnesium rod and a constant number of $\mathrm{Mg}^{2+}(\mathrm{aq})$ ions surround the rode. This dynamic equilibrium is shown in Figure 3.4 in which the negative charge on the Mg rod is balanced by the positive charges surrounded by it in the solution. Once this situation is achieved, we consider and define such a system as an electrode.

A system where a metal is in dynamic equilibrium with its ions can be defined as an electrode.

Figure 3.4 Behaviour of Mg metal in an aqueous solution at dynamic equilibrium

As with the above descriptions it is notable that the equilibrium exists in two ways; in one direction Mg solid is converted to $\mathrm{Mg}^{2+}(\mathrm{aq})$ ions while in the other direction $\mathrm{Mg}^{2+}(\mathrm{aq})$ ions in the solution are converted to Mg metal. In other words, Mg oxidizes in one direction and $\mathrm{Mg}^{2+}(\mathrm{aq})$ reduces in the other direction indicating that the overall system exhibits an oxidation-reduction couple.

Accordingly, we can get the idea that a charge separation occurs at the interface between metal and the solution/water. The tendency of this charge separation depends on the activity of metal. For example if we use a rod of Cu metal, the charge separation will be less compared to that of Mg . This relates the activity of metals described in electrochemistry (detailed discussion of this will appear in a later section).

Figure 3.5 Behaviour of Mg and Cu metals in an aqueous solutions at dynamic equilibrium. As Cu is less reactive than $\mathrm{Mg}, \mathrm{Cu}$ forms its $\mathrm{Cu}^{2+}$ ions less readily.

In general any ions which do break away are more likely to reclaim their electrons and stick back on to the metal again. The equilibrium position can still reachable, but there will be less charge on the metal, and fewer metal ions in solution as compared in Figure 3.5.

Once systems are in dynamic equilibrium, two reactions can be written as given below and it will also be possible to compare the positions of equilibrium of the two systems.

$$
\begin{align*}
& \mathrm{Mg}^{2+}(\mathrm{aq})+2 \mathrm{e} \rightleftharpoons \mathrm{Mg}(\mathrm{~s})  \tag{1}\\
& \mathrm{Cu}^{2+}(\mathrm{aq})+2 \mathrm{e} \rightleftharpoons \mathrm{Cu}(\mathrm{~s}) \tag{2}
\end{align*}
$$

According to Figure 3.5, the position of the equilibrium (1) is further to the left than that of the equilibrium (2).

It has to be noted the way that the two equilibria are written. By convention, all these equilibria are usually written with the electrons on the left-hand side of the equation that is as a reduction reaction.

As the position of equilibrium is different in the above two cases, the ability to reach the equilibrium may be expressed by introducing some numbers and that can be directly related to the term electrode potential which is simply an attempt to attach some numbers to these differing positions of equilibria. In principle, that is quite easy to do. In the case of magnesium, there is a large difference between the negativeness of the metal and the positiveness of the solution around it. In the copper case, the difference is much less and this can be used to understand the potential which arises due to the charge separation at the interface of the particular electrode.

This potential difference can be recorded as a voltage meaning that the bigger the difference between the positiveness and the negativeness, the bigger the voltage. Unfortunately, that voltage is impossible to measure by connecting a device to the above mentioned systems.

Even though, it would be easy to connect a voltmeter to the piece of metal, the problem is how a connection is made to the solution. If any probe is put into the solution a similar sort of equilibrium would happen around it. Therefore, the best measure would be some sort of combination of the effects at the probe and the piece of metal of interest.

That means, it is not required to measure the absolute voltage between the metal and the solution. It is enough to compare the voltage with a standardized system called a reference electrode and the system used is called a standard hydrogen electrode (SHE) which is shown in Figure 3.6.

As we know from the unit 12 (Equilibrium), the position of any equilibrium can be changed by changing conditions. That means the conditions must be standardized so that you can make fair comparisons.

In the standard hydrogen electrode the following conditions are used: $101325 \mathrm{~Pa} \sim 100 \mathrm{kPa}, 1 \mathrm{~atm}$ pressure of hydrogen gas, the temperature of $298 \mathrm{~K}\left(25^{\circ} \mathrm{C}\right)$ and $1.0 \mathrm{~mol} \mathrm{dm}^{-3}$ concentration of the hydrogen ions in the solution.

## G.C.E. (A/L) CHEMISTRY: UNIT 13 Electrochemistry

Figure 3.6 The standard hydrogen electrode
In this electrode, as the hydrogen gas flows over the porous platinum, an equilibrium is established between hydrogen molecules and hydrogen ions in solution which is catalyzed by platinum.

$$
2 \mathrm{H}^{+}(\mathrm{aq})+2 \mathrm{e} \rightleftharpoons \mathrm{H}_{2}(\mathrm{~g})
$$

Now let us see how we would measure the potential of a given electrode. In this measurement, the standard hydrogen electrode is attached to the electrode system for example, a piece of magnesium in a solution containing magnesium ions as considered earlier; a conducting Pt wire is introduced to connect the voltmeter and a salt bridge is introduced as shown in Figure 3.7.

Figure 3.7 Measurement of electrode potential using the standard hydrogen electrode

The salt bridge is introduced to complete the electrical circuit making a liquid junction. It is just a glass tube filled with a solution of an electrolyte like potassium nitrate. The ends are "stoppered" by bits of cotton wool or sometimes with agar gel to prevent mixing of the contents in the salt bridge with the contents of the two beakers. Each electrode on one side is defined as a half-cell.

It has to be noted that the electrolyte in the salt bridge is chosen so that it doesn't react with the contents of either beaker.

Once the two electrodes are connected two equilibria are set up on the two electrodes as follows.

$$
\begin{aligned}
\mathrm{Mg}^{2+}(\mathrm{aq})+2 \mathrm{e} & \rightleftharpoons \mathrm{Mg}(\mathrm{~s}) \\
2 \mathrm{H}^{+}(\mathrm{aq})+2 \mathrm{e} & \rightleftharpoons \mathrm{H}_{2}(\mathrm{~g})
\end{aligned}
$$

Magnesium has a much higher ability to form its ions than hydrogen does. Therefore, position of the $\mathrm{Mg} / \mathrm{Mg}^{2+}$ equilibrium will be more to the left than that of the $\mathrm{H}_{2} / \mathrm{H}^{+}$ equilibrium. This means that there is a much greater build-up of electrons on the piece of magnesium than on platinum. Therefore, there is a major difference between the charges on the two electrodes and hence a potential difference which can be measured with a voltmeter.

The value of potential mentioned above for $\mathrm{Mg}^{2+}(\mathrm{aq}) / \mathrm{Mg}(\mathrm{s})$ is actually the standard electrode potential of the $\mathrm{Mg}^{2+}(\mathrm{aq}) / \mathrm{Mg}(\mathrm{s})$ system.

The potential difference measured when a metal / metal ion electrode is coupled to a hydrogen electrode under standard conditions is known as the standard electrode potential of that metal / metal ion combination. This means that each $E^{\circ}$ value shows whether the position of the equilibrium lies to the left or right of the hydrogen equilibrium. The difference in the positions of equilibrium causes the number of electrons built up on the metal electrode and the platinum of the hydrogen electrode to be different. Here, as a convention the number of electrons produced on the Pt surface is considered to be negligible. The standard cell potential $E^{0}$ of the standard hydrogen electrode is taken as 0.00 V at room temperature. The potential difference produced is measured as a voltage having units of volts (V).

As we know that magnesium has the greater amount of negativeness, the voltage measured would be 2.37 V and the voltmeter would show magnesium as the negative electrode and the hydrogen electrode as positive. Therefore, the standard electrode potential of the $\mathrm{Mg}^{2+}(\mathrm{aq}) / \mathrm{Mg}(\mathrm{s})$ electrode is recorded as $E^{0}=-2.37 \mathrm{~V}$.

## G.C.E. (A/L) CHEMISTRY: UNIT 13 Electrochemistry

In the case when a similar measurement is done with the $\mathrm{Cu}^{2+}(\mathrm{aq}) / \mathrm{Cu}(\mathrm{s})$ electrode, copper forms its ions less readily than hydrogen does.

$$
\begin{aligned}
& \mathrm{Cu}^{2+}(\mathrm{aq})+2 \mathrm{e} \rightleftharpoons \mathrm{Cu}(\mathrm{~s}) \\
& 2 \mathrm{H}^{+}(\mathrm{aq})+2 \mathrm{e} \rightleftharpoons \mathrm{H}_{2}(\mathrm{~g})
\end{aligned}
$$

Therefore, the equilibrium in the hydrogen electrode lies further to the left. As a result there will be less build-up of electrons on copper than that is on the platinum of the hydrogen electrode. Therefore, there is less difference between the electrical charges on the two electrodes, so the voltage measured will be less (only +0.34 volts).

The other major change is that this time the copper is the more positive (less negative) electrode. The voltmeter will show the hydrogen electrode as the negative electrode and the copper electrode as the positive electrode and hence the electrode potential is recorded as +0.34 V .
(If any current flows, the voltage measured drops. In order to make proper comparisons, it is important to measure the maximum possible voltage in any situation. This is called the electromotive force or e.m.f. Details of this will be discussed in coming sections).

## Electrode notations

The hydrogen electrode is represented as below.

From the above descriptions we know that the standard electrode potential of a metal / metal ion combination is the potential difference measured when that metal / metal ion electrode is coupled to a hydrogen electrode under the standard conditions.

The measurement of electrode potentials allows us to determine the position of the metal/ metal ion equilibrium with respect to the equilibrium involving hydrogen.

A few typical standard electrode potentials are shown in the table below.

| Metal $/$ metal ion combination | $E^{\circ} / \mathrm{V}$ |
| :--- | :---: |
| $\mathrm{Mg}^{2+}(\mathrm{aq}) / \mathrm{Mg}(\mathrm{s})$ | -2.37 |
| $\mathrm{Zn}^{2+}(\mathrm{aq}) / \mathrm{Zn}(\mathrm{s})$ | -0.76 |
| $\mathrm{Cu}^{2+}(\mathrm{aq}) / \mathrm{Cu}(\mathrm{s})$ | +0.34 |
| $\mathrm{Ag}^{+}(\mathrm{aq}) / \mathrm{Ag}(\mathrm{s})$ | +0.80 |

Comparing these with the $E^{\circ}$ values, it can be seen that the ones whose positions of equilibrium lie furthest to the left have the most negative $E^{\circ}$ values. That is because they form ions more readily leaving more electrons behind on the metal. Those which don't release electrons readily have positions of equilibrium further to the right. Their $E^{\circ}$ values get progressively more positive.

In addition to these metal-metal ion electrodes, there are other types of electrodes as discussed below.

### 3.2.2 Metal - insoluble salt electrode

In order to define an electrode it is necessary to have oxidized and reduced species of the same element to be present. Accordingly, if a metal is in contact with the solid salt of the same metal, such electrodes are called metal - insoluble salt type. Examples for such electrodes are calomel electrode and silver-silver chloride electrode. Figure 3.8 shows details of the calomel electrode. A Pt wire is used to establish the electrical connection with an external circuit. A saturated solution of KCl is used for the electrical conductance.

Figure 3.8 Calomel electrode
Silver - silver chloride is another example for metal-insoluble salt type of an electrode. The essential components of this electrode comprise a silver wire coated with AgCl which

## G.C.E. (A/L) CHEMISTRY: UNIT 13 Electrochemistry

is in contact with the KCl electrolyte. An important part of silver - silver chloride electrode is the tip (ceramic, quartz, vycor tip, glass fibre) that connects electrode with the external solution. Figure 3.9 illustrates silver-silver chloride electrode.

$$
\mathrm{AgCl}(\mathrm{~s})+\mathrm{e} \rightarrow \mathrm{Ag}(\mathrm{~s})+\mathrm{Cl}^{-}(\mathrm{aq})
$$

Figure 3.9 Silver - silver chloride electrode
In general, calomel electrode and silver - silver chloride electrode are also known as reference electrodes as potential of these electrodes remains almost constant during experiment time.

### 3.2.3 Gas electrodes

## Hydrogen electrode

Standard Hydrogen Electrode is an example for a gas electrode. The standard conditions used here are $1.0 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{H}^{+}$ion concentration, 1 atm pressure for $\mathrm{H}_{2}$ gas, and temperature of the system is at 298 K . This hydrogen electrode is called the standard electrode as the potential of this electrode is defined as 0.00 V as described earlier.

$$
2 \mathrm{H}^{+}(\mathrm{aq})+2 \mathrm{e} \rightleftharpoons \mathrm{H}_{2}(\mathrm{~g})
$$

## Chlorine electrode

Chlorine is well known as an oxidizing agent. Since the electrochemical series is about ranking substances according to their oxidizing or reducing ability, it makes some insights to the electrode reactions with gases like chlorine. Again, as has been done above, we can measure the position of this equilibrium relative to the hydrogen equilibrium.

$$
\mathrm{Cl}_{2}(\mathrm{~g})+2 \mathrm{e} \rightleftharpoons 2 \mathrm{Cl}^{-}(\mathrm{aq})
$$

Note that as usual, the equilibrium is still written with the electrons on the left-hand side of the equation. That's why the chlorine gas has to appear on the left-hand side rather than on the right indicating the reduction during the reaction. For this chlorine electrode, a half-cell can be built as similar to the hydrogen electrode by bubbling chlorine gas over a platinum electrode, which is immersed in a solution containing chloride ions with a concentration of $1.0 \mathrm{~mol} \mathrm{dm}^{-3}$.
The notation of writing the cell looks like this.

$$
\mathrm{Pt}(\mathrm{~s})\left|\mathrm{Cl}_{2}(\mathrm{~g})\right| \mathrm{Cl}^{-}(\mathrm{aq})
$$

It can be noted that the chloride ions are losing electrons and hence the cell has a positive potential difference.

### 3.2.4 Redox electrodes

These types of electrodes are frequently observed in redox reactions. Both oxidized and the reduced species must be present in the solution when defining a particular redox electrode. A Pt wire can be used to establish the electrical connection with the external circuit. Such a redox type of electrode is given in Figure 3.10.

## $\mathrm{Fe}^{2+} / \mathrm{Fe}^{3+}$ redox electrode system

Iron(II) ions can easily be oxidized to iron(III) ions, and iron(III) ions are fairly easily reduced to iron(II) ions. The equilibrium for this can be written as follows.

$$
\mathrm{Fe}^{3+}(\mathrm{aq})+\mathrm{e} \rightleftharpoons \mathrm{Fe}^{2+}(\mathrm{aq})
$$

To measure the redox potential of this, a platinum electrode can be inserted into a beaker containing a solution of both iron(II) and iron(III) ions ( $1.0 \mathrm{~mol} \mathrm{dm}^{-3}$ with respect to each), and couple this to a hydrogen electrode.

Figure 3.10 $\mathrm{The}_{\mathrm{Fe}^{2+} / \mathrm{Fe}^{3+} \text { redox electrode system }}$

- When writing electrode in standard notation, phase boundaries are separated by a vertical line """

E,g. Gas electrodes: $\mathrm{Pt}(\mathrm{s})\left|\mathrm{O}_{2}(\mathrm{~g})\right| \mathrm{OH}^{-}(\mathrm{aq})$

- Physical states must be included next to each chemical species and conditions should be included where possible.
E.g. Redox electrodes: $\mathrm{Pt}(\mathrm{s}) \mid \mathrm{Fe}^{2+}\left(\mathrm{aq}, 1 \mathrm{~mol} / \mathrm{dm}^{3}\right), \mathrm{Fe}^{3+}\left(\mathrm{aq}, 1 \mathrm{~mol} / \mathrm{dm}^{3}\right)$

The following table summarizes the types of different electrodes with some examples.
Table 3.4 Summary of different types of electrodes

| Type of electrode | Standard notation | Redox couple | Reduction half reaction |
| :---: | :---: | :---: | :---: |
| Metal metal ion | $\mathbf{M}(\mathbf{s}) \mid \mathbf{M ~}^{\mathbf{n +}}(\mathbf{a q})$ | $\mathbf{M}(\mathbf{s}) / \mathbf{M ~}^{\mathbf{n +}}(\mathbf{a q})$ | $\mathbf{M}^{\mathbf{n +}}(\mathbf{a q})+\mathrm{ne} \rightarrow \mathbf{M}(\mathrm{s})$ |
|  | $\mathrm{Zn}(\mathrm{s}) \mid \mathrm{Zn}^{2+}(\mathrm{aq})$ | $\mathrm{Zn}(\mathrm{s}) / \mathrm{Zn}^{2+}(\mathrm{aq})$ | $\mathrm{Zn}^{2+}(\mathrm{aq})+2 \mathrm{e} \rightarrow \mathrm{Zn}(\mathrm{s})$ |
| Metal insoluble salt | $\mathbf{M}(\mathrm{s})\left\|\mathbf{M} \mathbf{X}_{\mathbf{n}}(\mathbf{s})\right\| \mathbf{X}^{-}(\mathbf{a q})$ | $\mathbf{M}(\mathbf{s}) / \mathbf{M X} \mathbf{n}_{\mathbf{n}}(\mathbf{s})$ | $\begin{gathered} \text { MX(s) + ne } \rightarrow \\ \mathbf{n M ( s )}+\mathbf{X X}^{\cdot}(\mathrm{aq}) \\ \hline \end{gathered}$ |
|  | $\mathrm{Ag}(\mathrm{s})\|\mathrm{AgCl}(\mathrm{s})\| \mathrm{Cl}^{-}(\mathrm{aq})$ | $\mathrm{Ag}(\mathrm{s}) / \mathrm{Ag}^{+}(\mathrm{aq})$ | $\begin{aligned} & \mathrm{AgCl}(\mathrm{~s})+\mathrm{e} \rightarrow \\ & \mathrm{Ag}(\mathrm{~s})+\mathrm{Cl}^{-}(\mathrm{aq}) \\ & \hline \end{aligned}$ |
|  | $\mathrm{Pt}(\mathrm{s})\|\mathrm{Hg}(1)\| \mathrm{Hg}_{2} \mathrm{Cl}_{2}(\mathrm{~s}) \mid \mathrm{Cl}^{-}(\mathrm{aq})$ | $\mathrm{Hg}\left(\mathrm{l} / \mathrm{Hg}_{2} \mathrm{Cl}_{2}(\mathrm{~s})\right.$ | $\begin{gathered} \mathrm{Hg}_{2} \mathrm{Cl}_{2}(\mathrm{~s})+2 \mathrm{e} \rightarrow \\ 2 \mathrm{Hg}(\mathrm{l})+2 \mathrm{Cl}^{-}(\mathrm{aq}) \end{gathered}$ |
| Gas | $\mathbf{P t}(\mathbf{s})\|\mathbf{X} \mathbf{( g )}\| \mathbf{X}^{+}(\mathbf{a q})$ | $\mathbf{X}_{2}(\mathrm{~g}) / \mathbf{X}^{+}(\mathbf{a q})$ | $\mathbf{X}^{+}(\mathrm{aq})+\mathrm{e} \rightarrow 1 / 2 \mathbf{X}_{2}(\mathrm{~g})$ |
|  | $\mathrm{Pt}(\mathrm{s})\left\|\mathrm{X}_{2}(\mathrm{~g})\right\| \mathrm{X}^{-}(\mathrm{aq})$ | $\mathrm{X}^{-}(\mathrm{aq}) / \mathrm{X}_{2}(\mathrm{~g})$ | $1 / 2 \mathrm{X}_{2}(\mathrm{~g})+\mathrm{e} \rightarrow \mathrm{X}^{-}(\mathrm{aq})$ |
|  | $\mathrm{Pt}(\mathrm{s})\left\|\mathrm{H}_{2}(\mathrm{~g})\right\| \mathrm{H}^{+}(\mathrm{aq})$ | $\mathrm{H}_{2}(\mathrm{~g}) / \mathrm{H}^{+}(\mathrm{aq})$ | $\mathrm{H}^{+}(\mathrm{aq})+\mathrm{e} \rightarrow 1 / 2 \mathrm{H}_{2}(\mathrm{~g})$ |
|  | $\mathrm{Pt}(\mathrm{s})\left\|\mathrm{O}_{2}(\mathrm{~g})\right\| \mathrm{OH}^{-}(\mathrm{aq})$ | $\mathrm{OH}^{-}(\mathrm{aq}) / \mathrm{O}_{2}(\mathrm{~g}) \mid$ | $\begin{aligned} & 2 \mathrm{O}_{2}(\mathrm{~g})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})+4 \mathrm{e} \rightarrow \\ & 4 \mathrm{OH}^{-}(\mathrm{aq}) \end{aligned}$ |

|  | $\mathrm{Pt}(\mathrm{s}) \mid \mathrm{Sn}^{2+}(\mathrm{aq}), \mathrm{Sn}^{4+}(\mathrm{aq})$ | $\mathrm{Sn}^{2+}(\mathrm{aq}) / \mathrm{Sn}^{4+}(\mathrm{aq})$ | $\mathrm{Sn}^{4+}(\mathrm{aq})+2 \mathrm{e} \rightarrow \mathrm{Sn}^{2+}(\mathrm{aq})$ |

Note: When writing any electrode reaction, a single arrow is used when there is a current passing through (not in equilibrium) and an equilibrium arrow is used when the electrode is isolated. Also, it is compulsory to mention the physical state of the chemical species whenever electrode reactions are written.

As indicated in above examples it is necessary to note that the electrode potentials of halfcells are given as redox potentials (the potential of the redox reaction).

Therefore, by arranging various redox equilibria in the order of their standard electrode potentials (redox potentials) we can build up the electrochemical series. The most negative $E^{\circ}$ values are placed at the top of the electrochemical series, and the most positive at the bottom as summarized in Table 3.5.

Table 3.5 Standard reduction potentials of selected electrodes at 298 K

| Reduction half reaction | Standard reduction potential ( $E^{\boldsymbol{\theta}}$ / V) |
| :---: | :---: |
| $\mathrm{Li}^{+}(\mathrm{aq})+\mathrm{e} \rightarrow \mathrm{Li}(\mathrm{s})$ | -3.05 |
| $\mathrm{K}^{+}(\mathrm{aq})+\mathrm{e} \rightarrow \mathrm{K}(\mathrm{s})$ | -2.93 |
| $\mathrm{Ca}^{2+}(\mathrm{aq})+2 \mathrm{e} \rightarrow \mathrm{Ca}(\mathrm{s})$ | -2.87 |
| $\mathrm{Na}^{+}(\mathrm{aq})+\mathrm{e} \rightarrow \mathrm{Na}(\mathrm{s})$ | -2.71 |
| $\mathrm{Mg}^{2+}(\mathrm{aq})+2 \mathrm{e} \rightarrow \mathrm{Mg}(\mathrm{s})$ | -2.36 |
| $\mathrm{Al}^{3+}(\mathrm{aq})+3 \mathrm{e} \rightarrow \mathrm{Al}(\mathrm{s})$ | -1.66 |

| $\mathrm{Cl}_{2}(\mathrm{~g})+2 \mathrm{e} \rightarrow 2 \mathrm{Cl}^{-}(\mathrm{aq})$ | +1.36 |
| $\mathrm{Au}^{3+}(\mathrm{aq})+3 \mathrm{e} \rightarrow \mathrm{Au}(\mathrm{s})$ | +1.40 |
| $\mathrm{S}_{2} \mathrm{O}_{8}{ }^{2-}(\mathrm{aq})+2 \mathrm{e} \rightarrow 2 \mathrm{SO}_{4}{ }^{2-}(\mathrm{aq})$ | +2.05 |
| $\mathrm{F}_{2}(\mathrm{~g})+2 \mathrm{e} \rightarrow 2 \mathrm{~F}^{-}(\mathrm{aq})$ | +2.87 |

## Reducing agents and oxidizing agents

As we know, a reducing agent reduces some other chemical species. That means that a reducing agent gives electrons to another chemical species. Conversely, an oxidizing agent oxidizes something else by accepting electrons.

According to the above electrochemical series, magnesium is good at giving away electrons to form its ions. Hence Magnesium is a good reducing agent. On the other hand, copper doesn't form its ions very readily, and its ions easily pick up electrons to convert to metallic copper. Hence, copper(II) ions must be a good as an oxidizing agent.

It is with this idea we notice that the metals at the top of the series (with negative standard electrode potential) are good at giving away electrons hence act as good reducing agents. The reducing ability of the metal increases going up the series.

Metal ions at the bottom of the series are good at picking up electrons. These are good oxidizing agents. The oxidizing ability of the metal ions increases down the series.

In other words, the more negative the $E^{\circ}$ value, the position of the equilibrium to the left and the tendency of the metal to lose electrons. Therefore, the more negative the value, a particular species is stronger reducing agent. The situation is opposite for the species at the bottom of the electrochemical series as these are good oxidizing agents. Therefore, metals such as $\mathrm{Na}, \mathrm{Mg}, \mathrm{Zn}$, etc. with negative reduction potential prefer to be in ionic state rather elemental state and shows higher reactivity. The opposite is true for the species listed below the potential of standard hydrogen electrode. When two metals are in contact, metals with higher negative standard potential prefer to be in ionic state, thus can be used to reduce ions of the other metal in contact.

### 3.3 Electrochemical cells

### 3.3.1 Construction of an electrochemical cell

So far we have considered combinations of a hydrogen electrode with the different electrodes as we measure standard reduction potential. It is interesting to consider what happens if a zinc half-cell is combined with a copper half-cell through a voltmeter and the solutions are connected via a salt bridge as shown in Figure 3.11.

Figure 3.11 An electrochemical cell prepared by connecting two half-cells of Zn and Cu

This type of set up is defined as an electrochemical cell which consists of two electrodes in contact with an electrolyte. In an electrochemical cell, there can be a common electrolyte or may be in different electrolytes. In the latter case, electrodes in two different electrolytes are connected via a salt bridge. The potential generated due to presence of two different electrolytes in the electrode compartments is called "liquid junction potential". However, this potential can be minimized if two electrolytes are joined using a salt bridge. A salt bridge is essentially a medium consisting of an electrolyte such as KCl or $\mathrm{KNO}_{3}$ which is jellified with agar in an inverted "U" shaped tube. The two ends of liquid junction are dipped in respective electrode units. This liquid junction can also be made by a permeable membrane/ diaphragm/ porous partitioning which allows ions to pass through it.

The two equilibria which are set up in the above half cells are as follows.

$$
\begin{array}{ll}
\mathrm{Zn}^{2+}(\mathrm{aq})+2 \mathrm{e} \rightleftharpoons \mathrm{Zn}(\mathrm{~s}) & E^{0}=-0.76 \mathrm{~V} \\
\mathrm{Cu}^{2+}(\mathrm{aq})+2 \mathrm{e} \rightleftharpoons \mathrm{Cu}(\mathrm{~s}) & E^{0}=+0.34 \mathrm{~V}
\end{array}
$$

The negative sign of the $E^{\circ}$ value for zinc shows that it releases electrons more readily than hydrogen does. The positive sign of the copper $E^{\circ}$ for copper shows that it releases electrons less readily than hydrogen.

This allows us to compare the two electrode equilibria directly. The position of the zinc equilibrium lies further to the left than the copper equilibrium. Therefore, the voltmeter will show that the zinc as the negative electrode and copper is the (relatively) positive one. It will indicate a voltage showing the difference between them.

Usually the high resistivity voltmeter is used stop any current flow in the circuit. If the circuit is constructed without a voltmeter but two half-cells still connected, then electrons will flow from where there are lot of them (on zinc) to where there are fewer (on copper). The movement of the electrons is thus an electrical current. At this situation the equilibrium is disturbed, hence we may apply Le Chatelier's Principle to understand the changes in the system due to current flow. Here following two opposing effects are noticed.

On one side, electrons are flowing away from the zinc equilibrium, according to Le Chatelier's principle; the position of equilibrium will move to replace the lost electrons.

On the other side of copper, electrons are added onto the piece of copper in the copper equilibrium. According to Le Chatelier's Principle, the position of equilibrium will move to remove these extra electrons. As a result, the changes occur as shown in the following sketch and can be illustrated by Figure 3.12.

Figure 3.12 A Galvanic cell prepared by combining two half-cells of Zn and Cu without a voltmeter

In the above system, if electrons continue to flow from Zn side to Cu side, the positions of equilibrium keeps on shifting. Therefore, the two equilibria essentially turn into two one-direction (side) reactions. The zinc continues to ionize, and the copper(II) ions keep on collecting up electrons and the two reactions can be written as follows.

$$
\begin{aligned}
& \mathrm{Zn}(\mathrm{~s}) \rightarrow \mathrm{Zn}^{2+}(\mathrm{aq})+2 \mathrm{e} \\
& \mathrm{Cu}^{2+}(\mathrm{aq})+2 \mathrm{e} \rightarrow \mathrm{Cu}(\mathrm{~s})
\end{aligned}
$$

Therefore, on the whole we can see that there is a net chemical reaction going on in which zinc is going into solution as zinc ions, and is giving electrons to copper(II) ions to turn them into metallic copper. The overall reaction can be obtained by adding the above two reactions which are called half-cell reactions.

In the above, it is seen that the current is produced in the cell due to the occurrence of a spontaneous chemical reaction. Therefore, it is possible to categorize electrochemical cells into two types. If the cell is able to produce electricity through a spontaneous reaction, then it is called a galvanic cell or a voltaic cell. If the reaction is not spontaneous then an external source of current is required to operate the cell. Such a cell is called an electrolytic cell.

In a galvanic cell, oxidation and reduction reactions are responsible for the operation of the cell. When the cell is in operation, electrons released at one electrode due to oxidation travels to the other electrode resulting in reduction of the chemical species in that compartment. The electrode at which oxidation takes place is called the anode and the electrode at which reduction takes place is called the cathode. The overall cell reaction is obtained as combination of reduction and oxidation half reactions. Therefore, for the galvanic cell consisting of Zn and Cu electrodes which is named as Daniel cell, the overall reaction is given by the sum of the two half reactions.

Cathode (reduction half reaction): $\mathrm{Cu}^{2+}(\mathrm{aq})+2 \mathrm{e} \rightarrow \mathrm{Cu}(\mathrm{s})$ (Right hand side electrode, RHE)

Anode (oxidation half reaction) : $\mathrm{Zn}(\mathrm{s}) \rightarrow \mathrm{Zn}^{2+}(\mathrm{aq})+2 \mathrm{e} \quad$ (Left hand side electrode, LHE)

Cell reaction $\quad: \mathbf{C u}^{\mathbf{2 +}}(\mathbf{a q})+\mathbf{Z n}(\mathbf{s}) \rightarrow \mathbf{C u}(\mathbf{s})+\mathbf{Z n}^{2+}(\mathbf{a q})$

It has to be noted that, if an external opposite potential is applied to the galvanic cell described above and increased slowly, we find that the reaction continues to take place till the opposing voltage reaches the value 1.1 V at which the reaction stops altogether and no current flows through the cell. Any further increase in the external potential again starts the reaction but in the opposite direction $\left(\mathbf{C u}(\mathbf{s})+\mathbf{Z n}^{\mathbf{2}}(\mathbf{a q}) \rightarrow \mathbf{C u}^{\mathbf{2 +}}(\mathbf{a q})+\mathbf{Z n}(\mathbf{s})\right)$.

It now functions as an electrolytic cell, a device which uses electrical energy to carry non-spontaneous chemical reactions. Here, it is important to pay attention to the voltage of 1.1 V stated above and how it arises for the presently considered Daniel cell. This can be understood as follows.

The oxidation and reduction half reactions occur in two different parts of the Daniell cell. The reduction half reaction occurs at the copper electrode while the oxidation half reaction occurs at the zinc electrode. These two portions of the cell are also called halfcells or redox couples as mentioned earlier. The copper electrode may be called the reduction half-cell and the zinc electrode, the oxidation half-cell.

In a galvanic cell, the half-cell in which oxidation takes place (anode) has a negative potential with respect to the solution. The other half-cell in which reduction taking place (cathode) has a positive potential with respect to the solution. Thus, there exists a potential difference between the two electrodes and as soon as the switch is in the on position the electrons flow from negative electrode to positive electrode. The direction of current flow is opposite to that of the electron flow. The potential difference between the two electrodes of a galvanic cell is called the cell potential and is measured in volts. The cell potential is the difference between the electrode potentials (reduction potentials) of the cathode and anode. It is called the cell electromotive force (emf) of the cell when no current is drawn through the cell. It is now an accepted convention that we keep the anode on the left and the cathode on the right while representing a galvanic cell. If there is an electrochemical cell where two electrodes are in two different electrolyte solution, there is an additional potential difference arise across the boundary. This is termed as "liquid junction potential". The contribution of liquid junction potential can be minimized using a salt bridge to join two electrolyte solutions.

A Galvanic cell is generally represented by putting a vertical line between metal and electrolyte solution and putting a double vertical line between the two electrolytes connected by a salt bridge. Following points are important in writing the cell notation.

- Electrode corresponding to the oxidation half reaction in a cell is always written on the left hand side and electrode where reduction half reaction take place is written on the right hand side.
- Phase boundaries are represented by a vertical bar "|"
- If there is a liquid junction potential present then a ": " is used between two electrodes
- If there is a salt bridge (i.e. no liquid junction potential), two electrodes are separated by a double vertical bars "||"
- Indication of the physical state is compulsory for all species and indication of conditions such as concentration, pressure, temperature must be in cooperated if known.

According to the cell notation, the Daniel cell above can be written as,

$$
\left.\mathrm{Zn}(\mathrm{~s}) \mid \mathrm{Zn}^{2+}\left(\mathrm{aq}, 1.0 \mathrm{~mol} \mathrm{dm}^{-3}\right)\right)\left|\left|\mathrm{Cu}^{2+}\left(\mathrm{aq}, 1.0 \mathrm{~mol} \mathrm{dm}{ }^{-3}\right)\right| \mathrm{Cu}(\mathrm{~s})\right.
$$

Other examples are:

$$
\begin{aligned}
& \operatorname{Mg}(\mathrm{s})\left|\mathrm{Mg}^{2+}\left(\mathrm{aq}, 1.0 \mathrm{~mol} \mathrm{dm}^{-3}\right) \| \mathrm{H}^{+}\left(\mathrm{aq}, 1.0 \mathrm{~mol} \mathrm{dm}^{-3}\right)\right| \mathrm{H}_{2}(\mathrm{~g}) \mid \operatorname{Pt}(\mathrm{s}) \\
& \operatorname{Pt}(\mathrm{s})\left|\mathrm{H}_{2}(\mathrm{~g})\right| \mathrm{H}^{+}(\mathrm{aq}) \| \mathrm{Cl}^{-}(\mathrm{aq})\left|\mathrm{Cl}_{2}(\mathrm{~g})\right| \operatorname{Pt}(\mathrm{s})
\end{aligned}
$$

When a common electrolyte HCl is used for both electrodes,

$$
\mathrm{Pt}(\mathrm{~s})\left|\mathrm{H}_{2}(\mathrm{~g})\right| \mathrm{H}^{+}(\mathrm{aq}), \mathrm{Cl}^{-}(\mathrm{aq})|\mathrm{AgCl}(\mathrm{~s})| \mathrm{Ag}(\mathrm{~s})
$$

Under this convention the emf of the cell is positive and is given by the potential of the half-cell on the right hand side minus the potential of the half-cell on the left hand side i.e.,

$$
\begin{aligned}
& E_{\text {cell }}=E_{\text {right }}-E_{\text {left }} \\
& \text { or } \\
& E_{\text {cell }}=E_{\text {cathode }}-E_{\text {anode }}
\end{aligned}
$$

Thus, for the cell that we are considering,

$$
\begin{aligned}
& E_{\text {cell }}=E_{\mathrm{Cu}^{2+}}{ }_{(\mathrm{aq}) / \mathrm{Cu}(\mathrm{~s})}-E_{\mathrm{Zn}}{ }^{2+}\left({ }_{(\mathrm{qq}) / \mathrm{Zn}(\mathrm{~s})}\right. \\
& E_{\text {cell }}=0.34 \mathrm{~V}-(-0.76 \mathrm{~V}) \\
& E_{\text {cell }}=+1.10 \mathrm{~V}
\end{aligned}
$$

This can further be understood by the following example.
Consider the cell reaction:

$$
\mathrm{Cu}(\mathrm{~s})+2 \mathrm{Ag}^{+}(\mathrm{aq}) \rightarrow \mathrm{Cu}^{2+}(\mathrm{aq})+2 \mathrm{Ag}(\mathrm{~s})
$$

Half-cell reactions:
Cathode (reduction): $\quad 2 \mathrm{Ag}^{+}(\mathrm{aq})+2 \mathrm{e} \rightarrow 2 \mathrm{Ag}(\mathrm{s})$
Anode (oxidation): $\quad \mathrm{Cu}(\mathrm{s}) \rightarrow \mathrm{Cu}^{2+}(\mathrm{aq})+2 \mathrm{e}$
It can be seen that the sum of half reactions leads to the overall reaction in the cell and that silver electrode acts as the cathode and copper electrode acts as the anode. The cell can be represented as:

$$
\left.\mathrm{Cu}(\mathrm{~s}) \mid \mathrm{Cu}^{2+} \mathrm{aq}\right) \| \mathrm{Ag}^{+}(\mathrm{aq}) \mid \mathrm{Ag}(\mathrm{~s})
$$

and we have,

$$
E_{\mathrm{cell}}=E_{\mathrm{right}}-E_{\mathrm{left}}=E_{\mathrm{Ag}^{+}}{ }^{+} \mathrm{Ag}-E_{\mathrm{Cu}^{2+}}{ }^{2+} / \mathrm{Cu}
$$

Therefore, by substituting corresponding reduction potentials of the half-cells the value of the emf of the cell can be estimated.

$$
E_{\text {cell }}=+0.80 \mathrm{~V}-(0.34 \mathrm{~V})=+0.46 \mathrm{~V}
$$

This reaction can also be treated like below.
Both of these $E^{\circ}$ values are positive. $E_{\mathrm{Ag}+/ \mathrm{Ag}}=+0.80 \mathrm{~V}$ and $E_{\mathrm{Cu}^{2+} / \mathrm{Cu}}=+0.34 \mathrm{~V}$ indicating that neither copper nor silver produces ions and releases electrons as easily as hydrogen does.

However, of the two, copper releases electrons more readily as it has a less positive $E^{0}$ value. In a cell, copper would have the greater buildup of electrons, and is the negative electrode. If copper and silver are connected by a bit of a wire, electrons would flow from the copper to silver as described below.

Therefore, it can be confirmed that the given cell reaction is feasible.

## Example 3.2

Following diagrams indicate different versions of Daniel cells. Write the cell in standard notation.
(a)

(b)

## Answer

(a) In this diagram, there is a liquid junction between the two different electrolytes. Therefore, cell notation is $\mathrm{Zn}(\mathrm{s})\left|\mathrm{Zn}^{2+}(\mathrm{aq}): \mathrm{Cu}^{2+}(\mathrm{aq})\right| \mathrm{Cu}(\mathrm{s})$.
(b) In this diagram, the presence of liquid junction potential is minimized using a salt bridge. Therefore, cell notation is $\mathrm{Zn}(\mathrm{s})\left|\mathrm{Zn}^{2+}(\mathrm{aq}) \| \mathrm{Cu}^{2+}(\mathrm{aq})\right| \mathrm{Cu}(\mathrm{s})$.

### 3.3.2 Factors affecting the electrode potential

The potential of an electrode depends on several factors as listed below.

- temperature
- concentration of the electrolyte
- nature of the electrolyte
- pressure of the gas
- type of electrolyte

For an electrochemical reaction to take place, metal ions must collide with the electrode surface with proper orientation and energy. Therefore, temperature and concentration of the electrolyte are important when determining the electrode potential. The nature of the electrolyte is also important when considering charge transport during the operation of the cell. This is discussed under section 3.1.1. When gas electrodes are used, it is very
important to mention the pressure of the gas as it can be used to define number of molecules in a unit volume.

The electrode potential of silver-silver chloride measured with respect to SHE is 0.220 V . However, if the concentration of KCl electrolyte used is $0.10 \mathrm{~mol} \mathrm{dm}^{-3}$, then the electrode potential is changed to 0.288 V and in the case of $1.00 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{KCl}$ it is further changed to 0.235 V .

### 3.3.3 Different types of electrochemical cells

Electrochemical cells are used to convert chemical energy to electrical energy. Therefore, such electrochemical cells are employed in many aspects of daily life where electrical items are operated with 'batteries'. In these cells chemical reactions occur when two electrodes are connected externally using a conductor to generate the current. When the cell reaction cannot be reversed by providing electrical energy, such electrochemical cells are called "primary cells" (i.e. non rechargeable). Normal Leclanche cell in Figure 3.11(a) and Daniel cell in Figure 3.11 (b) are examples for primary cells.

Figure 3.11 (a) Normal Leclanche cell (b) Daniel cell

Figure 3.12 (a) Schematic diagram of a lead accumulator (b) Lead accumulator (c) Commercial lead accumulator (car battery)

Another type of cell that is used in daily life is the lead accumulator. This is more commonly known as the "car battery". These cells can be recharged by reversin̨ ${ }^{1 \cdots \ldots}$ reaction (rechargeable), so these cells are referred as "secondary cells". Figure 3.12 illustrates a lead accumulator.

Table 3.6 Summary on different types of electrochemical cells

| Electrochemical cell | Normal Leclanche cell (primary cell) | Daniel cell (primary cell) | Lead accumulator (secondary cell) |
| :---: | :---: | :---: | :---: |
| Electrolyte | $\mathrm{NH}_{4} \mathrm{Cl} / \mathrm{ZnCl}_{2}$ | $\mathrm{ZnSO}_{4}(\mathrm{aq}) / \mathrm{CuSO}_{4}(\mathrm{aq})$ | Dil. $\mathrm{H}_{2} \mathrm{SO}_{4}$ |

| (-) pole | Zn | Zn | Pb |
| Reaction at ( ${ }^{+}$) pole <br> (Cathode reaction) | $\begin{gathered} 2 \mathrm{NH}_{4}^{+}(\mathrm{aq})+2 \mathrm{MnO}_{2}(\mathrm{~s})+2 \mathrm{e} \\ \rightarrow \mathrm{Mn}_{2} \mathrm{O}_{3}(\mathrm{~s})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})+ \\ 2 \mathrm{NH}_{3}(\mathrm{~g}) \end{gathered}$ | $\mathrm{Cu}^{2+}(\mathrm{aq})+2 \mathrm{e} \rightarrow \mathrm{Cu}(\mathrm{~s})$ | (During discharging) $\begin{gathered} \mathrm{PbO}_{2}(\mathrm{~s})+4 \mathrm{H}^{+}(\mathrm{aq})+\mathrm{SO}_{4}^{2-} \\ (\mathrm{aq})+2 \mathrm{e} \rightarrow \mathrm{PbSO}_{4}(\mathrm{~s})+ \\ 2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \end{gathered}$ |
| Reaction at (-) pole <br> (Anode reaction) | $\mathrm{Zn}(\mathrm{s}) \rightarrow \mathrm{Zn}^{2+}(\mathrm{aq})+2 \mathrm{e}$ | $\mathrm{Zn}(\mathrm{s}) \rightarrow \mathrm{Zn}^{2+}(\mathrm{aq})+2 \mathrm{e}$ | (During discharging) $\begin{gathered} \mathrm{Pb}(\mathrm{~s})+\mathrm{SO}_{4}{ }^{2-}(\mathrm{aq}) \rightarrow \\ \mathrm{PbSO}_{4}(\mathrm{aq})+2 \mathrm{e} \end{gathered}$ |
| Cell reaction | $\begin{gathered} \mathrm{Zn}(\mathrm{~s})+2 \mathrm{NH}_{4}^{+}(\mathrm{aq})+ \\ 2 \mathrm{MnO}_{2}(\mathrm{~s}) \rightarrow \mathrm{Zn}^{2+}(\mathrm{aq})+ \\ \mathrm{Mn}_{2} \mathrm{O}_{3}(\mathrm{~s})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})+2 \mathrm{NH}_{3}(\mathrm{~g}) \end{gathered}$ | $\begin{gathered} \mathrm{Zn}(\mathrm{~s})+\mathrm{Cu}^{2+}(\mathrm{aq}) \rightarrow \mathrm{Zn}^{2+}(\mathrm{aq}) \\ +\mathrm{Cu}(\mathrm{~s}) \end{gathered}$ | (During discharging) $\begin{gathered} \mathrm{PbO}_{2}(\mathrm{~s})+4 \mathrm{H}^{+}(\mathrm{aq})+\mathrm{Pb}(\mathrm{~s}) \rightarrow \\ 2 \mathrm{PbSO}_{4}(\mathrm{~s})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \end{gathered}$ |

### 3.4 Electrolysis

In Galvanic cells, a spontaneous chemical reaction can convert chemical energy to electrical energy. However, in daily life we come across situations where nonspontaneous redox reactions must be carried out to produce useful items. Examples are electroplating where precious metals like silver (Ag) can be coated on a less expensive metal to get a more appealing cover or can be used to coat a protective metal layer. In such a situation, the corresponding non-spontaneous chemical reaction can be driven forward giving electrical energy from outside. Conducting a non-spontaneous chemical reaction using electrical energy from outside is known as electrolysis. A direct current is passed through a molten substance or substance dissolved in a suitable solvent when conducting electrolysis. Chemical reactions at electrodes will result in the desired product.

When conducting electrolysis, the electrode connected to the positive terminal of the external source of electricity (battery) is the positive electrode (anode). The electrode connected to the negative terminal is the negative electrode (cathode). When conducting electrolysis, positive ions in the solution are attracted towards the negative electrode (cathode) and undergo reduction. The opposite happens at the anode where negatively charged ions in the solution are oxidized.

### 3.4.1 Electrolysis of water

Water is a very stable chemical substance. Therefore, electrolysis of water to produce hydrogen gas and oxygen gas is not a spontaneous chemical reactions under atmospheric conditions ( $1 \mathrm{~atm}, 25{ }^{\circ} \mathrm{C}, \Delta G^{\theta}$ is $474.4 \mathrm{~kJ} \mathrm{~mol}^{-1}$ ). In order electrolyse water, external electrical energy must be supplied to carry out the redox reaction.

Electrolysis of water can be performed using the setup given in the Figure 3.14.

Figure 3.14 Experimental set up for electrolysis of water
The main ionic species in pure water are $\mathrm{H}^{+}(\mathrm{aq})$ ion and $\mathrm{OH}^{-}(\mathrm{aq})$ ions each having a concentration of $1 \times 10^{-7} \mathrm{~mol} \mathrm{dm}^{-3}$. Therefore, dilute $\mathrm{H}_{2} \mathrm{SO}_{4}\left(0.10 \mathrm{~mol} \mathrm{dm}^{-3}\right)$ is added to
water to enrich $\mathrm{H}^{+}(\mathrm{aq})$ ions in solution. This facilitates conducting electricity due to the presence of sufficient number of ionic species than in pure water.

The overall reaction is given by

Anode (oxidation):
Cathode (reduction):
Overall:

$$
\begin{aligned}
& 2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightarrow \mathrm{O}_{2}(\mathrm{~g})+4 \mathrm{H}^{+}(\mathrm{aq})+4 \mathrm{e}^{-} \\
& \frac{4 \mathrm{H}^{+}(\mathrm{aq})+4 \mathrm{e}^{-} \rightarrow 2 \mathrm{H}_{2}(\mathrm{~g})}{\left.\mathbf{2} \mathbf{H}_{2} \mathbf{O}(\mathbf{l}) \rightarrow \mathbf{2}\right)} \mathbf{H}_{2}(\mathbf{g})+\mathbf{O}_{2}(\mathrm{~g})
\end{aligned}
$$

It is clear from the overall reaction of electrolysis that $\mathrm{H}_{2} \mathrm{SO}_{4}$ concentration has no effect on the electrolysis.

## Example 3.3 <br> Using standard electrode potentials listed in Table 3.5, calculate the minimum voltage required for the electrolysis of water.

## Answer

Standard electrode potentials for the electrolysis of water is given below.

$$
\begin{array}{lll}
\text { Anode (oxidation): } & 2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightarrow \mathrm{O}_{2}(\mathrm{~g})+4 \mathrm{H}^{+}(\mathrm{aq})+4 \mathrm{e}^{-} & \left(E^{\ominus}=1.23 \mathrm{~V}\right) \\
\text { Cathode (reduction): } & \begin{array}{ll}
4 \mathrm{H}^{+}(\mathrm{aq})+4 \mathrm{e}^{-} \rightarrow 2 \mathrm{H}_{2}(\mathrm{~g}) & \left(E^{\ominus}=0.00 \mathrm{~V}\right) \\
\text { Overall: } & \mathbf{2 H}_{\mathbf{2}} \mathbf{O}(\mathbf{l}) \rightarrow \mathbf{2 H}_{\mathbf{2}}(\mathbf{g})+\mathbf{O}_{\mathbf{2}}(\mathbf{g})
\end{array} &
\end{array}
$$

$E^{\ominus}$ cell $=E^{\ominus}$ cathode $-E^{\ominus}$ anode $=0 \mathrm{~V}-(1.23 \mathrm{~V})=\mathbf{- 1 . 2 3} \mathbf{V}$
Since $E^{\ominus}$ cell is negative, $\Delta G^{\ominus}$ is positive. Therefore, reaction is not spontaneous. In order to conduct this reactions external electrical supply must give a minimum voltage of 1.23 V .

### 3.4.2 Electrolysis of $\mathrm{CuSO}_{4}(\mathrm{aq})$ using copper electrodes

Electrolysis of $\mathrm{CuSO}_{4}$ (aq) solution using Cu electrodes is a method practiced commercially to purify copper. In general raw copper is extracted from the ore using carbon. However, copper produced in this way comprises many impurities. Therefore, pure Cu can be obtained when $\mathrm{CuSO}_{4}(\mathrm{aq})$ solution is electrolysed with a positive electrode (anode) made of impure Cu and a negative electrode (cathode) of pure Cu . When the system is connected to an electrical source (e.g. 9V battery), impure Cu rod (anode) will dissolve providing $\mathrm{Cu}^{2+}$ ions to the solution while more Cu will deposit on the pure Cu rod (cathode) growing it's size.
Anode (oxidation):
$\mathrm{Cu}(\mathrm{s}) \rightarrow \mathrm{Cu}^{2+}(\mathrm{aq})+2 \mathrm{e}^{-}$
Cathode (reduction):
$\mathrm{Cu}^{2+}(\mathrm{aq})+2 \mathrm{e}^{-} \rightarrow \mathrm{Cu}(\mathrm{s})$

Figure 3.15 Experimental set up for electrolysis of $\mathrm{CuSO}_{4}(\mathrm{aq})$

### 3.4.3 Electrolysis of $\mathrm{CuSO}_{4}(\mathrm{aq})$ using inert electrodes

A scenario different from above is observed when electrolysis of $\mathrm{CuSO}_{4}$ solution is conducted using inert electrodes such as Pt or graphite. In this case, at the anode $\mathrm{O}_{2}$ gas is released and deposition of Cu is observed at the cathode. The experimental set up used here is much similar to Figure 3.15. The only change is the use of inert electrodes.

$$
\begin{array}{ll}
\text { Anode (oxidation): } & 2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightarrow \mathrm{O}_{2}(\mathrm{~g})+4 \mathrm{H}^{+}(\mathrm{aq})+4 \mathrm{e}^{-} \\
\text {Cathode (reduction): } & \underline{\mathrm{Cu}^{2+}(\mathbf{a q})+2 \mathrm{e}^{-} \rightarrow \mathbf{C u}(\mathrm{s})} \\
\text { Overall reaction: } & \mathbf{2 \mathbf { C u } ^ { 2 + } ( \mathbf { a q } ) + \mathbf { 2 } \mathbf { H } _ { \mathbf { 2 } } \mathbf { O } ( \mathbf { l } ) \rightarrow \mathbf { 2 C u } ( \mathbf { s } ) + \mathbf { O } _ { \mathbf { 2 } } ( \mathbf { g } ) + \mathbf { 4 H ^ { + } } ( \mathbf { a q } )}
\end{array}
$$

In this experiment if ions that are present near the cathode (negative electrode) are considered, reduction of $\mathrm{Cu}^{2+}$ ions to Cu metal $(+0.34 \mathrm{~V})$ is easier compared to reduction $f \mathrm{H}^{+}$ions to $\mathrm{H}_{2}$ gas $(0.00 \mathrm{~V})$ according to the values of standard reduction potentials listed in Table 13.5. Similarly, when anode (positive electrode) is concerned, $\mathrm{SO}_{4}{ }^{2-}$ and $\mathrm{OH}^{-}$ ions are attracted. Among these ions, oxidation of water $(+1.23 \mathrm{~V})$ is more feasible than the oxidation of $\mathrm{SO}_{4}{ }^{2-}(\mathrm{aq})$ ion $(+2.05 \mathrm{~V})$. Therefore, at the anode, $\mathrm{O}_{2}$ gas is released by oxidation of water.

### 3.4.4 Electrolysis of $\mathrm{NaCl}(\mathrm{aq})$ using inert electrodes

When considering electrolysis of $\mathrm{NaCl}(\mathrm{aq})$ solution, it is important to analyze oxidation and reduction reactions that can happen at the corresponding electrodes first. Then comparison of standard reduction potentials of competing reactions can be used to predict final products. Following are competing reduction reactions taking place near the cathode.

$$
\begin{array}{ll}
2 \mathrm{H}^{+}(\mathrm{aq})+2 \mathrm{e} \rightarrow \mathrm{H}_{2}(\mathrm{~g}) & E^{\ominus}=0.00 \mathrm{~V} \\
2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})+2 \mathrm{e} \rightarrow \mathrm{H}_{2}(\mathrm{~g})+2 \mathrm{OH}^{-}(\mathrm{aq}) & E^{\ominus}=-0.83 \mathrm{~V} \\
\mathrm{Na}^{+}(\mathrm{aq})+\mathrm{e} \rightarrow \mathrm{Na}(\mathrm{~s}) & E^{\ominus}=-2.71 \mathrm{~V} \tag{3}
\end{array}
$$

When considering standard reduction potentials, the most probable reduction is reaction (1). However, this reaction requires standard conditions and also, $\left[\mathrm{H}^{+}(\mathrm{aq})\right]$ in water is too low $\left(10^{-7} \mathrm{~mol} \mathrm{dm}^{-3}\right)$. Hence it is not possible under ordinary laboratory conditions. The reaction (3) which involves reduction of $\mathrm{Na}^{+}(\mathrm{aq})$ ion cannot happen due to large negative potential. Therefore, when electrolysis of $\mathrm{NaCl}(\mathrm{aq})$ solution is considered, the most possible reduction reaction that can happen at the cathode is (2) which involves reduction of water to produce $\mathrm{H}_{2}(\mathrm{~g})$ and $\mathrm{OH}^{-}(\mathrm{aq})$ ions.

In order to determine the most possible oxidation reactions that happen at the anode, first it is important to list all oxidation reactions.

$$
\begin{align*}
& 2 \mathrm{Cl}^{-}(\mathrm{aq}) \rightarrow \mathrm{Cl}_{2}(\mathrm{~g})+2 \mathrm{e}  \tag{4}\\
& 2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightarrow \mathrm{O}_{2}(\mathrm{~g})+4 \mathrm{H}^{+}(\mathrm{aq})+4 \mathrm{e} \tag{5}
\end{align*}
$$

Then we can write the standard reduction potentials for the reduction of above reactions before predicting the most possible reaction.

$$
\begin{array}{ll}
\mathrm{Cl}_{2}(\mathrm{~g})+2 \mathrm{e} \rightarrow 2 \mathrm{Cl}^{-}(\mathrm{aq}) & E^{\ominus}=+1.36 \mathrm{~V} \\
\mathrm{O}_{2}(\mathrm{~g})+4 \mathrm{H}^{+}(\mathrm{aq})+4 \mathrm{e} \rightarrow 2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) & E^{\ominus}=+1.23 \mathrm{~V} \tag{5’}
\end{array}
$$

According to above data, reduction reaction of ( $4^{\prime}$ ) is more feasible than ( $5^{\prime}$ ) i.e. oxidation of (5) is more feasible than (4). Therefore, according to standard reduction potentials, most favourable oxidation reaction is (5). However, when this experiment is conducted the gas evolved is $\mathrm{Cl}_{2}$ and $\mathrm{NOT} \mathrm{O}_{2}$ ! That is because the actual potential that needs to be supplied for the reaction to take place is sometimes greater than the standard reduction potential. This extra potential is termed over potential (Detailed discussion of over potential is beyond the scope of G. C. E. (A/L) Chemistry syllabus). In other words, standard reduction potentials can be used to obtain minimum voltage values that can be supplied to drive the reaction of interest; however, actual voltage may be higher due to presence of over potentials. Therefore, $\mathrm{Cl}_{2}(\mathrm{~g})$ is observed, because over potential for reaction (5) (release of $\mathrm{O}_{2}(\mathrm{~g})$ ) could be much greater than for the reaction (4). Thus reaction (4) requires less potential to be supplied than for reaction (5).

Finally, the reactions taking place at the cathode and anode when electrolyzing $\mathrm{NaCl}(\mathrm{aq})$ solution using inert electrodes can be written as follows.

```
Anode (oxidation):
Cathode (reduction):
Overall reaction:
```

$2 \mathrm{Cl}^{-}(\mathrm{aq}) \rightarrow \mathrm{Cl}_{2}(\mathrm{~g})+2 \mathrm{e}$
$2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})+2 \mathrm{e} \rightarrow \mathrm{H}_{2}(\mathrm{~g})+2 \mathrm{OH}^{-}(\mathrm{aq})$
$2 \mathrm{Cl}^{-}(\mathrm{aq})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightarrow \mathrm{Cl}_{2}(\mathrm{~g})+\mathrm{H}_{2}(\mathrm{~g})+2 \mathrm{OH}^{-}(\mathrm{aq})$

### 3.4.5 Electrolysis of $\mathbf{N a C l}(\mathbf{l})$ (molten $\mathbf{N a C l}$ ) using inert electrodes

NaCl exits in solid form at room temperature, thus does not conduct electricity due to absence of mobile ionic species. However, if the temperature is raised to more than the melting point of $\mathrm{NaCl}(\mathrm{s})$ (i.e. $>801^{\circ} \mathrm{C}$ ), molten $\mathrm{NaCl}(\mathrm{l})$ consists of mobile $\mathrm{Na}^{+}$ions and
$\mathrm{Cl}^{-}$ions. Therefore, electrolysis of molten NaCl will result in reduction of $\mathrm{Na}^{+}$ion to produce Na metal and $\mathrm{Cl}_{2}$ gas as the oxidation product.

> Anode (oxidation):
> Cathode (reduction):
> Overall reaction:

$2 \mathrm{Cl}^{-}(\mathrm{l}) \rightarrow \mathrm{Cl}_{2}(\mathrm{~g})+2 \mathrm{e}$
$\mathrm{Na}^{+}(\mathrm{l})+\mathrm{e} \rightarrow \mathrm{Na}(\mathrm{l})$

$$
2 \mathrm{Cl}^{-}(\mathrm{l})+2 \mathrm{Na}^{+}(\mathrm{l}) \rightarrow \mathrm{Cl}_{2}(\mathrm{~g})+2 \mathrm{Na}(\mathrm{l})
$$

According to the standard reduction potentials listed in Table 3.5, the minimum voltage that should be supplied for the overall reaction to take place is 4.07 V . However, in practice, much higher voltage is required to drive the reaction due to the presence of a large over potential associated with the reaction. Industrially Na metal is extracted by this method by electrolyzing molten NaCl solution. The industrial set up is known as the Downs cell.

## Example 3.4 <br> Predict the gases evolved at the cathode and anode when $\mathrm{Na}_{2} \mathrm{SO}_{4}(\mathrm{aq})$ solution is electrolyzed using inert electrodes.

Answer
Step 1: Identify possible oxidation reactions that can happen near the anode (Hint:
Anions are likely to be oxidized at the anode) and write standard reduction potentials using Table 13.5.
$2 \mathrm{SO}_{4}{ }^{2-}(\mathrm{aq}) \rightarrow \mathrm{S}_{2} \mathrm{O}_{8}{ }^{2-}(\mathrm{aq})+2 \mathrm{e} \quad$ (Standard reduction potential $\left.=+2.05 \mathrm{~V}\right) \ldots . .(1)$
$2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightarrow \mathrm{O}_{2}(\mathrm{~g})+4 \mathrm{H}^{+}(\mathrm{aq})+4 \mathrm{e}^{-} \quad($ Standard reduction potential $=+1.23 \mathrm{~V}) \ldots . .(2)$
When over potential is not considered, the lower the standard reduction potential easier is to oxidize when the direction of oxidation is concerned.
At the anode $\mathrm{O}_{2}$ gas will be evolved.

Step 2: Identify possible reduction reactions that can happen near the cathode (Hint: cations are likely to be reduced at the cathode) and write standard reduction potentials using Table 3.5.
$2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})+2 \mathrm{e} \rightarrow \mathrm{H}_{2}(\mathrm{~g})+2 \mathrm{OH}^{-}(\mathrm{aq}) \quad($ Standard reduction potential $=-0.83 \mathrm{~V}) \ldots . .(3)$
$\mathrm{Na}^{+}(\mathrm{aq})+\mathrm{e} \rightarrow \mathrm{Na}(\mathrm{s}) \quad$ (Standard reduction potential $\left.=-2.71 \mathrm{~V}\right) \ldots .$. (4)
The higher the negative value of standard reduction potential of a species, it is more likely to be in the oxidized form. Reduction of $\mathrm{Na}^{+}$has a higher negative value compared to reduction of water as listed above. Therefore, $\mathrm{Na}^{+}$tends to stay in the $\mathrm{Na}^{+}$ state while $\mathrm{H}_{2} \mathrm{O}$ will be reduced at the cathode to produce $\mathrm{H}_{2}$ gas.

Both half reactions involve oxidation and reduction of water instead of $\mathrm{OH}^{-}$ions and $\mathrm{H}^{+}$ions. That it is because $\mathrm{Na}_{2} \mathrm{SO}_{4}$ is a neutral salt which keeps the solution at a pH of approximately 7. Therefore, $\mathrm{H}_{2} \mathrm{O}$ oxidize and reduce itself due to the absence of high concentrations of $\mathrm{OH}^{-}$and $\mathrm{H}^{+}$ions.

Step 3: Write the overall reaction combining cathode and anode reactions.

Anode (oxidation):
$2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightarrow \mathrm{O}_{2}(\mathrm{~g})+4 \mathrm{H}^{+}(\mathrm{aq})+4 \mathrm{e}$
Cathode (reduction): $4 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})+4 \mathrm{e} \rightarrow 2 \mathrm{H}_{2}(\mathrm{~g})+4 \mathrm{OH}^{-}(\mathrm{aq})$
Overall reaction:

$$
2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightarrow \mathrm{O}_{2}(\mathrm{~g})+2 \mathrm{H}_{2}(\mathrm{~g})
$$

### 3.4.6 Quantitative aspects of electrolysis

Michael Faraday was the first scientist who described the quantitative aspects of electrolysis. Faraday's laws stem from what has been discussed earlier.

## Faraday's laws of electrolysis

The following well known Faraday's two laws of electrolysis is mainly used for quantitative analysis in electrolysis.
(i) First Law: The amount of chemical reaction which occurs at any electrode during electrolysis by a current is proportional to the quantity of electricity passed through the electrolyte (solution or melt).
(ii) Second Law: The amounts of different substances liberated by the same quantity of electricity passing through the electrolytic solution are proportional to their chemical equivalent weights (Atomic Mass of Metal / Number of electrons required to reduce the cation).

The quantity of electricity $Q$, passed is given by

$$
Q=I t
$$

The amount of electricity (or charge) required for oxidation or reduction depends on the stoichiometry of the electrode reaction. For example, in the reaction:

$$
\mathrm{Ag}^{+}(\mathrm{aq})+\mathrm{e} \rightarrow \mathrm{Ag}(\mathrm{~s})
$$

one mole of electrons is required for the reduction of one mole of silver ions. We know that charge on one electron is equal to $1.6021 \times 10^{-19} \mathrm{C}$.
Therefore, the charge on one mole of electrons is equal to:
$N_{A} \times 1.6021 \times 10^{-19} \mathrm{C}=6.02 \times 10^{23} \mathrm{~mol}^{-1} \times 1.6021 \times 10^{-19} \mathrm{C}=96487 \mathrm{C} \mathrm{mol}^{-1}$

This quantity of electricity is called Faraday (constant) and is represented by the symbol F.

For approximate calculations we use $1 \mathrm{~F} \simeq 96500 \mathrm{C} \mathrm{mol}^{-1}$.
For the electrode reactions:

$$
\begin{aligned}
\mathrm{Mg}^{2+}(\mathrm{aq})+2 \mathrm{e} & \rightarrow \mathrm{Mg}(\mathrm{~s}) \\
\mathrm{Al}^{3+}(\mathrm{aq})+3 \mathrm{e} & \rightarrow \mathrm{Al}(\mathrm{~s})
\end{aligned}
$$

it is obvious that one mole of $\mathrm{Mg}^{2+}$ and $\mathrm{Al}^{3+}$ require 2 moles of electrons $(2 \mathrm{~F})$ and 3 moles of electrons $(3 \mathrm{~F})$ respectively.

## Application of Faraday constant to electrochemical calculations

When electrolysis experiments are conducted, it is important to know quantitatively the yield of the products at the cathode and the anode. The yield is associated with the current passed through the cell for a known period of time. For example, consider following reduction reactions.

$$
\begin{gathered}
\mathrm{Na}^{+}(\mathrm{aq})+\mathrm{e} \rightarrow \mathrm{Na}(\mathrm{~s}) \\
2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})+2 \mathrm{e} \rightarrow \mathrm{H}_{2}(\mathrm{~g})+2 \mathrm{OH}^{-}(\mathrm{aq})
\end{gathered}
$$

In order to produce 1 mole of $\mathrm{Na}(\mathrm{s})$ metal, 1 mole of electrons must be used to reduce $\mathrm{Na}^{+}$. Similarly, to produce 1 mole of $\mathrm{H}_{2}$ gas, 2 moles of electrons are required.

The charge in coulombs for a one mole of electrons is given by the Faraday constant which is $96485 \mathrm{C} \mathrm{mol}^{-1}$. Therefore, if the charge in coulombs passed through the cell is known, then the amount product of consumption of reactants can be calculated. In general, the current passed though the electrolytic cell for given period of time is known. Then the following relationship can be used to calculate the charge associated during that period of time when the current passed through is given in amperes (A) and time in seconds (s).

Current $(\mathrm{A}) \times$ time $(\mathrm{s}) \rightarrow$ coulombs $(\mathrm{C}) \rightarrow$ moles of electrons $\rightarrow$ moles of product or reactant

## Example 3.5

Calculate the volumes of gases evolved at the cathode and anode when dil. $\mathrm{H}_{2} \mathrm{SO}_{4}(\mathrm{aq})$ solution is electrolyzed using inert electrodes for a period of 5 h passing a current of 1.5 A under $25^{\circ} \mathrm{C}$ and 1 atm pressure.

## Answer

Step 1: Identify possible oxidation reactions that can happen near the anode (Hint: anions are likely to be oxidized at the anode) and write standard reduction potentials using Table 13.5.

$$
\begin{align*}
& 2 \mathrm{SO}_{4} 2^{2-}(\mathrm{aq}) \rightarrow \mathrm{S}_{2} \mathrm{O}_{8}{ }^{2-}(\mathrm{aq})+2 \mathrm{e} \quad(\text { Standard reduction potential }=+2.05 \mathrm{~V}) \ldots . .(1) \\
& 2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightarrow \mathrm{O}_{2}(\mathrm{~g})+4 \mathrm{H}^{+}(\mathrm{aq})+4 \mathrm{e}^{-}(\text {Standard reduction potential }=+1.23 \mathrm{~V}) \ldots . .(2)
\end{align*}
$$

As illustrated in Example 3.4, the reaction at the cathode is (2). Therefore, at the anode $\mathrm{O}_{2}$ gas is evolved.

Step 2: Identify possible reduction reactions that can happen near the cathode (Hint: Cations are likely to be reduced at the cathode) and write standard reduction potentials using Table 3.5.

$$
\begin{array}{ll}
2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})+2 \mathrm{e} \rightarrow \mathrm{H}_{2}(\mathrm{~g})+2 \mathrm{OH}^{-}(\mathrm{aq}) & (\text { Standard reduction potential }=-0.83 \mathrm{~V}) \ldots \ldots(3) \\
\mathrm{H}^{+}(\mathrm{aq})+\mathrm{e} \rightarrow \mathrm{H}_{2}(\mathrm{~g}) & (\text { Standard reduction potential }=0.00 \mathrm{~V}) \ldots .(4)
\end{array}
$$

Since it is a dilute $\mathrm{H}_{2} \mathrm{SO}_{4}$ solution, there is sufficient $\mathrm{H}^{+}$concentration present for reaction (4) to take place preferably at the cathode. Therefore, the gas evolved at the cathode is $\mathrm{H}_{2}$ gas.

Step 3: Write the overall reaction combining cathode and anode reactions.
Anode (oxidation):

$$
2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightarrow \mathrm{O}_{2}(\mathrm{~g})+4 \mathrm{H}^{+}(\mathrm{aq})+4 \mathrm{e}
$$

Cathode (reduction):
$4 \mathrm{H}^{+}(\mathrm{aq})+4 \mathrm{e} \rightarrow 2 \mathrm{H}_{2}(\mathrm{~g})$
Overall reaction:
$2 \mathbf{H}_{2} \mathrm{O}(\mathrm{I}) \rightarrow \mathrm{O}_{2}(\mathrm{~g})+2 \mathrm{H}_{2}(\mathrm{~g})$
Step 4: Calculate the amount of charge passed through during electrolysis period.

$$
\begin{aligned}
\text { Charge }=\text { current }(\mathrm{A}) \times \text { time }(\mathrm{s}) & =1.5 \mathrm{~A} \times(5 \times 60 \times 60) \mathrm{s}=\mathbf{2 7 0 0 0} \mathrm{C} \\
\text { Amount of moles of electrons } & =27000 \mathrm{C} \times\left(1 / 96485 \mathrm{C} \mathrm{~mol}^{-1}\right) \\
& =\mathbf{0 . 2 8} \mathbf{~ m o l e s} \text { of electrons }
\end{aligned}
$$

Step 5: Calculate volume of $\mathrm{O}_{2}$ gas evolved at the anode
According to the oxidation half reaction,
4 moles of electrons $\rightarrow 1$ mole of $\mathrm{O}_{2}(\mathrm{~g})$
Amount of moles of $\mathrm{O}_{2}(\mathrm{~g})$ produced

$$
\begin{aligned}
& =0.28 \text { moles of electrons } \times \frac{1 \text { mole of } \mathrm{O}_{2}(\mathrm{~g})}{4 \text { moles of electrons }} \\
& =\mathbf{0 . 0 7} \text { moles of } \mathbf{O}_{\mathbf{2}}(\mathrm{g})
\end{aligned}
$$

Apply ideal gas equation to calculate volumes of $\mathrm{O}_{2}(\mathrm{~g})$ produce, $\mathrm{V}=\mathrm{nRT} / \mathrm{P}$

$$
\text { Volume of } \mathrm{O}_{2}(\mathrm{~g})=\left(0.07 \mathrm{~mol} \times 8.314 \mathrm{~J} \mathrm{~K}^{-1} \mathrm{~mol}^{-1} \times 298 \mathrm{~K}\right) / 1 \times 10^{5} \mathrm{~Pa}
$$

$$
=173.4 \times 10^{-5} \mathrm{~m}^{3}=\mathbf{1 . 7 3 4} \mathbf{~ d m}^{3}
$$

Step 5: Calculate the volume of $\mathrm{H}_{2}$ gas evolved at the cathode.
According to the reduction half reaction,
2 moles of electrons $\rightarrow 1$ moles of $\mathrm{H}_{2}(\mathrm{~g})$
Amount of moles of $\mathrm{H}_{2}(\mathrm{~g})$ produced

$$
\begin{aligned}
& =0.28 \text { moles of electrons } \times \frac{1 \text { mole of } \mathrm{H}_{2}(\mathrm{~g})}{2 \text { moles of electrons }} \\
& =\mathbf{0 . 1 4} \mathbf{m o l e s} \text { of } \mathbf{H}_{\mathbf{2}}(\mathrm{g})
\end{aligned}
$$

Apply ideal gas equation to calculate volumes of $\mathrm{H}_{2}(\mathrm{~g})$ produce, $\mathrm{V}=\mathrm{nRT} / \mathrm{P}$
Volume of $\mathrm{H}_{2}(\mathrm{~g})=\left(0.14 \mathrm{~mol} \times 8.314 \mathrm{~J} \mathrm{~K}^{-1} \mathrm{~mol}^{-1} \times 298 \mathrm{~K}\right) / 1 \times 10^{5} \mathrm{~Pa}$

$$
=346.8 \times 10^{-5} \mathrm{~m}^{3}=\mathbf{3 . 4 7} \mathrm{dm}^{3}
$$

### 3.4.7 Comparison of galvanic cells and electrolytic cells

The main difference between the two types of cells is the spontaneous nature of the cell reaction. In Galvanic cells, the cell reaction is spontaneous and chemical energy is converted to electrical energy. Therefore, electricity is produced in galvanic cells. The anode in a Galvanic cell is negatively charged due to electrons left behind during oxidation. The cathode is positively charged due to taking up of electrons for the reduction half reaction.

The opposite is taking place during electrolysis or in electrolytic cells. The overall cell reaction is not spontaneous. Therefore, it is necessary to pump electrons from an external source to proceeds the reaction. Therefore, a battery is used in electrolysis to supply electricity for the chemical reaction to take place. Here, the anode is connected to the positive terminal of the battery. The oxidation reaction taking place at the anode will generate electrons that are attracted towards the positive terminal of the battery. Therefore, the anode is positively charged. The opposite is true for the cathode and it is connected to the negative terminal of the battery. So the cathode in electrolytic cell is negatively charged.

## Message from the Director General

The National Institute of Education takes opportune steps from time to time for the development of quality in education. Preparation of supplementary resource books for respective subjects is one such initiative.

Supplementary resource books have been composed by a team of curriculum developers of the National Institute of Education, subject experts from the national universities and experienced teachers from the school system. Because these resource books have been written so that they are in line with the G. C. E. (A/L) new syllabus implemented in 2017, students can broaden their understanding of the subject matter by referring these books while teachers can refer them in order to plan more effective learning teaching activities.

I wish to express my sincere gratitude to the staff members of the National Institute of Education and external subject experts who made their academic contribution to make this material available to you.

Dr. (Mrs.) T. A. R. J. Gunasekara
Director General
National Institute of Education
Maharagama.

## Message from the Director

Since 2017, a rationalized curriculum, which is an updated version of the previous curriculum is in effect for the G.C.E (A/L) in the general education system of Sri Lanka. In this new curriculum cycle, revisions were made in the subject content, mode of delivery and curricular materials of the G.C.E. (A/L) Physics, Chemistry and Biology. Several alterations in the learning teaching sequence were also made. A new Teachers' Guide was introduced in place of the previous Teacher's Instruction Manual. In concurrence to that, certain changes in the learning teaching methodology, evaluation and assessment are expected. The newly introduced Teachers' Guide provides learning outcomes, a guideline for teachers to mould the learning events, assessment and evaluation.

When implementing the previous curricula, the use of internationally recognized standard textbooks published in English was imperative for the Advanced Level science subjects. Due to the contradictions of facts related to the subject matter between different textbooks and inclusion of the content beyond the limits of the local curriculum, the usage of those books was not convenient for both teachers and students. This book comes to you as an attempt to overcome that issue.

As this book is available in Sinhala, Tamil, and English, the book offers students an opportunity to refer the relevant subject content in their mother tongue as well as in English within the limits of the local curriculum. It also provides both students and teachers a source of reliable information expected by the curriculum instead of various information gathered from the other sources.

This book authored by subject experts from the universities and experienced subject teachers is presented to you followed by the approval of the Academic Affairs Board and the Council of the National Institute of Education. Thus, it can be recommended as a material of high standard.

## 1.Industrial Chemistry and Enviornmental Pollution

## Content

### 1.1 Industrial chemisty

1.1.1 Chemical industry
1.1.2 Requirements to be considered in establishing chemical industries
1.1.3 Use of raw materials for chemical industry
1.2 Extraction of magnesium - (DOW process)
1.3 Caustic soda (NaOH) production
1.4 Production of soap
1.5 Production of sodium carbonate (Solvay process/ ammonia soda method)
1.6 Production of ammonia
(Haber Bosch method)
1.7 Production of nitric acid (Ostwald method)
1.8 Production of sulphuric acid (Contact process)
1.9 Production of titanium dioxide from rutile
1.10 Extraction of iron

### 1.11 Polymers

1.11.1 Rubber and plastic
1.11.2 Natural rubber
1.11.3 Vulcanizing natural rubber
1.11.4 Addition substances used for the products related to polymer
1.12 Chemical products related to plant resources
1.12.1 Production of vinegar
1.12.2 Production of ethanol
1.12.3 Essential oils
1.12.4 Bio diesel
1.13 Chemistry of air pollution caused by industrial emissions
1.13.1 Acid rain
1.13.2 Global warming
1.13.3 Depletion of the ozone layer
1.13.4 Photochemical smog
1.14 Chemistry of water pollution caused by industrial discharges
1.14.1 Water cycle and water pollution
1.14.2 Water quality parameters
1.14.3 Waste water quality parameters

### 1.1 Industrial Chemistry

### 1.1.1 Chemical industries

Colossal changes occurred in the mode of production and the force of production during the periods identified as the first industrial revolution (1750-1850) and the second industrial revolution (1870-1914 or 1850-1940) in modern civilization. Along with the diversified market concepts (consumerism) based on the basic requirements of human, world scale productions and services speeds up making profits. Various types of technological tools and methods of productions were created for this. With industrialization, environmental and social problems tended to emerge. Hence more attention had to be paid to reduce the risk of environmental problems and disasters, optimize efficiency and increase productivity. Alongside the gaming of a special place by chemical industries in the process of industrial production, a field of study of which came to be known as Chemical Engineering emerged. Today it has become a well-established discipline.

Iron, ammonia, sulphuric acid, nitric acid, caustic soda and petroleum can be given as some of the main chemical products in the world. Specially medicines, monomers, polymers, lubricants and organic dyes are examples for the products manufactured using organic compounds obtained from the petroleum industry. Plastic and rubber goods, cosmetics, soap, detergents, adhesives, paper, glass, salt, sugar, used in day-to-day life are some more examples for the products of chemical industries. Production of salt using sea water is one of the chemical industries in our country.

Production of soap using major chemicals produced in the world, production of various materials and goods using natural rubber latex and production of cement, paint and glass are some of the chemical industries carried out in our country at present.

Chemical industries spread out and establish in global scale area diverse. They can be classified as chemical industries producing organic chemicals and inorganic chemicals. In addition, they can also be classified as industries which produce agrochemicals, medicine, lubricants, dyes, metals and other substances.

Only few industries are discussed as examples which are based on modern knowledge and technology. Paying attention on the enviornmental, health and social issues at present worldwide, the industries suitable to our country are considered. Management of the knowledge on such is an entrance to 'Industrial Chemistry' discussed here.

### 1.1.2 Requirements to be considered in establishing chemical industries

There are requirements that should be considered when establishing a chemical industry. Some of them are given below.

- Capital
- Supply of raw materials
- Labour
- Technology
- Assurance of the production process
- Assurance of continuity
- Waste products and methods of waste management.
- Strategies for preventing the addition of environmental pollutants by the industry.
- Site of installation
- Nature of power supply (fossil, solar energy, nucleic energy, bio mass) and cost
- Transport facilities and market
- Nature of probable accidents and strategies that can be adopted to prevent accidents
- Government rules, regulations and policies.

Safety of the production process and prevention of accidents are very important in chemical industry. For this some of the disasters occurred in relation to chemical industries should be investigated. On 21 September 1921, 500-600 people died at an explosion occurred in Oppau on of Germany. The explosion was caused by 4500 tons of a mixture of ammonium nitrate and ammonium sulphate meant to be used as fertilizers. Similarly, the accident at the Chernobil nuclear power station in Ukrane (26 April, 1986) claimed nearly 4000 human lives at once. Because of the Bhopal incident in India (27 December, 1984), about 8000 men and women had to lay down their lives within a period of one week. The reason for this was found to be the leakage of the highly poisonous gas methyl isocyanide. Therefore, it is very important to understand properly the real need of a chemical industry and the political, social, economic and environmental changes associated with it. Moreover, the understanding about the maintenance of the production process safely, efficiently and effectively is also great importance.

### 1.1.3 Use of raw materials of chemical industry

Raw materials are the substances that are supplied from outside for a chemical industry and which take part in the production process. Production of compounds such as $\mathrm{NaHCO}_{3}, \mathrm{H}_{2} \mathrm{SO}_{4}$ can be given as examples for this. In some chemical industries, chemical components contained in raw materials exist in the product as they were. That is chemical changes do not occur; but physical changes do occur. Paint production is an example for this.

Various raw materials are used for chemical industries. Different sources are used for this. For example, nitrogen gas is used as one of the raw materials to produce ammonia. Atmospheric air is the source from which this nitrogen is obtained. Atmospheric air is first liquefied; then $\mathrm{N}_{2}$ gas is separated by fractional distillation and used for ammonia production. But in the production of nitric acid, instead of pure oxygen gas, atmospheric air is directly used to obtain $\mathrm{NO}_{2}$ gas by oxidizing ammonia. In ammonia production (Haber process) though atmospheric air is the source for $\mathrm{N}_{2}$ gas, which is an essential raw material for it is obtained, in the manufacturing of nitric acid, atmospheric air itself
is used as a raw material. Thus, facts such as the way the entire production process is planned, expenditure and what level of purity should be maintained are useful to decide in which form the raw materials should be used.

When using a natural resource as a raw material, it is useful to take the following into consideration.

- Occuring in large deposits for long term usage
- Easy to reach
- Purity

Specially, crude oil is the source for the production of many basic organic compounds. Hydrogen gas obtained by cracking of hydrocarbons is used as an essential raw material for the production of ammonia. Coke is a non-renewable raw material used for the production of iron.

A brief account on the raw materials used for some products is given below.

## Air

a) Oxygen is needed as an active component in iron extraction, production of nitric acid and sulphuric acid. Atmospheric air is used as a raw material in these productions.
b) Atmospheric air is used as a natural source of nitrogen. Nitrogen gas obtained by liquefaction of air followed by fractional distillation is used as a raw material in manufacturing ammonia. In the process of separating nitrogen gas from atmospher, atmospheric air is used as a raw material.

When using atmospheric air for chemical industries, it could be identified as a source of nitrogen or oxygen gas

Fractional

## Water

Water is used for the production of sodium hydroxide and, nitric acid, sulphuric acid and calcium hydroxide. Sea water is not used as a source of water in these industries. The
reason for this is that various salts presents in sea water interfere with the production process and also get into the product as impurities. Hence it is very important to take care about the standards of the raw materials.

## NaCl

NaCl is obtained using sea water as a raw material or from the ores of rock salt. Caustic soda is produced using NaCl as a raw material. It is also used as raw material in the extraction of Na metal. Sea water can be counted as a source for the production of NaCl . But sea water cannot be used as a raw material for the production of caustic soda.

## Minerals

Minerals are non-renewable resources. For the extraction of metals such as iron, copper, nickel, aluminum and titanium, minerals containing those metals are used as raw materials. Also minerals containing phosphates are used for the production of phosphate fertilizers. As minerals are non-renewable resources, there could be a recycling process after using the products from minerals. Further, it is also important to use those products to produce useful substances that are long-lasting.

## Coal

Coal is a non-renewable resource. It is mainly used as a fuel. In extraction of iron, it is used as a fuel, a direct reductant as well as a raw material essential to generate CO which is a major reducing agent.

## Crude oil

Crude oil is a non-renewable resource. It is used as the main source of fuels such as petrol and diesel. Crude oil is the main source from which raw materials for the production of monomers for polymers, medicine and basic organic compounds are obtained. As this is a non-renewable resource, continuation of the productions based on it becomes a problem with its consumption. Another crisis is the increase in global warming caused by the carbon dioxide produced during the burning of fuel obtained from crude oil.

## Plants

Plants are very important resources for the production of various oils, latex (rubber latex), resins and medicine. Plant materials are known as biomass and used as fuel for industries and also as raw materials for the production of various orgnic compounds. As Plants is a renewable resource, it is a source that can be managed without disturbing the natural cycles in the environment. Industries which used petroleum oil to generate power have started to use biomass as an alternative source of energy. Industries in our country too are inclined towards this.

### 1.2 Extraction of Mg - Dow process

## Raw materials essential for extracting Mg by Dow process.

Minerals containing magnesium is abundant in the earth crust. But, extraction of Mg from sea water is more profitable.

Other than $\mathrm{Na}^{+}, \mathrm{Mg}^{2+}$ is the most abundance cation in sea water. In sea water, about $0.13 \%$ by weight is magnesium. The solution discarded at the last stage of producing salt from sea water is called bittern. As bittern contains significant amounts of magnesium ions, it is more suitable to use bittern to extract magnesium. Either sea water or disposable brine obtained after the reverse -osmosis of sea water is suitable for this. The main steps of this process can be briefly presented as follows.

## Step 1

The main aim of this step is the production of CaO , which is obtained by the thermal decomposition of limestone. Dolomite also can be used for this purpose.

$$
\begin{aligned}
& \mathrm{CaCO}_{3}(\mathrm{~s}) \stackrel{\Delta}{\rightleftharpoons} \mathrm{CaO}(\mathrm{~s})+\mathrm{CO}_{2}(\mathrm{~g}) \\
& \mathrm{CaCO}_{3} \mathrm{MgCO}_{3}(\mathrm{~s}) \rightleftharpoons \Delta \\
& \rightleftharpoons \\
& \mathrm{CaO}(\mathrm{~s})+\mathrm{MgO}(\mathrm{~s})+2 \mathrm{CO}_{2}(\mathrm{~g})
\end{aligned}
$$

As this reaction is reversible, by designing the thermal decompostion process, carbon dioxide gas is efficiently removed. Contamination of calcium oxide with calcium carbonate is a disadvantage.

## Step 2

The object of this step is to produce $\mathrm{Mg}(\mathrm{OH})_{2}$ from the solution containing $\mathrm{Mg}^{2+}$ ions. The oxides produced in the first step $(\mathrm{CaO}$ or CaO and MgO$)$ are reacted with bittern solution. Here, CaO reacts with water forming calcium hydroxide. $\mathrm{Ca}(\mathrm{OH})_{2}$ dissolves slightly in water giving $\mathrm{Ca}^{2+}$ and $\mathrm{OH}^{-}$ions. Since the solubility product of $\mathrm{Mg}(\mathrm{OH})_{2}$ is lower than that of $\mathrm{Ca}(\mathrm{OH})_{2}, \mathrm{Mg}^{2+}$ ions in the solution are precipitated as $\mathrm{Mg}(\mathrm{OH})_{2}$ by $\mathrm{OH}^{-}$ ions supplied by $\mathrm{Ca}(\mathrm{OH})_{2}$ with this, more and more $\mathrm{Ca}(\mathrm{OH})_{2}$ goes into solution releasing $\mathrm{OH}^{-}$ions without remaining $\mathrm{Ca}(\mathrm{OH})_{2}$ as precipitate, it dissolves. The amount of CaO required to precipitate the $\mathrm{Mg}^{2}+$ ions in the solution is added. Prcipitaion of $\mathrm{Ca}(\mathrm{OH})_{2}$ with $\mathrm{Mg}(\mathrm{OH})_{2}$ is a disadvantage.

$$
\begin{align*}
& \mathrm{CaO}(\mathrm{~s})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow \mathrm{Ca}(\mathrm{OH})_{2}(\mathrm{~s})  \tag{1}\\
& \mathrm{Ca}(\mathrm{OH})_{2}(\mathrm{~s}) \rightleftharpoons \Delta \mathrm{Ca}^{2+}(\mathrm{aq})+2 \mathrm{OH}^{-}(\mathrm{aq})  \tag{2}\\
& \mathrm{Mg}^{2+}(\mathrm{aq})+2 \mathrm{OH}^{-}(\mathrm{aq}) \longrightarrow \mathrm{Mg}(\mathrm{OH})_{2}(\mathrm{~s}) \tag{3}
\end{align*}
$$

## Step 3

$\mathrm{Mg}(\mathrm{OH})_{2}$ formed is filterd and removed and reacted with concentrated HCl to get $\mathrm{MgCl}_{2}$

$$
\mathrm{Mg}(\mathrm{OH})_{2}(\mathrm{~s})+2 \mathrm{HCl}(\mathrm{aq}) \longrightarrow \mathrm{MgCl}_{2}(\mathrm{aq})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

If burnt dolomite ( $\mathrm{MgO} . \mathrm{CaO}$ ) was used, CaO in it, reacts with the $\mathrm{Mg}^{2+}$ ions in the solution as above. But as MgO is insoluble in water, MgO is mixed with $\mathrm{Mg}(\mathrm{OH})_{2}$ precipitaed.

## Step 4

The solution is heated strongly to vaporize water. Then it is dried so that the amount of water of crystallization becomes considerably low. The dried salt contains about $16 \%$ (w/w) water.

$$
\begin{aligned}
& \mathrm{MgCl}_{2} \cdot 6 \mathrm{H}_{2} \mathrm{O}(\mathrm{~s}) \longrightarrow \mathrm{MgCl}_{2} \cdot 4 \mathrm{H}_{2} \mathrm{O}(\mathrm{~s})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \\
& \mathrm{MgCl}_{2} \cdot 4 \mathrm{H}_{2} \mathrm{O}(\mathrm{~s}) \longrightarrow \mathrm{MgCl}_{2} \cdot 2 \mathrm{H}_{2} \mathrm{O}(\mathrm{~s})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})
\end{aligned}
$$

First the solid formed is fused in the steel chambers where electrolysis is done and then it is electrolized. During heating for fusion, all the water in the salt gets completely removed by vaporization. The temperature in the cell is maintained within the range $700-800^{\circ} \mathrm{C}$. Since the melting points of $\mathrm{MgCl}_{2}$ and magnesium metal are $714^{\circ} \mathrm{C}$ and $650{ }^{\circ} \mathrm{C}$ respectively, the temperature of the fused salt should be maintained above those melting temperatures. As Mg metal formed during the electrolysis of the fused salt exists in the molten state, its withdrawal from the cell is easier. The density of molten Mg at its melting point is $1.584 \mathrm{~g} \mathrm{~cm}^{-3}$ while the density of fused $\mathrm{MgCl}_{2}$ (at the melting point) is $1.68 \mathrm{~g} \mathrm{~cm}^{-3}$. Thus, fused Mg metal floats on fused $\mathrm{MgCl}_{2}$
Reaction at the anode (graphite) :

$$
2 \mathrm{Cl}^{-}(\mathrm{l}) \longrightarrow \mathrm{Cl}_{2}(\mathrm{~g})+2 \mathrm{e}
$$

$\mathrm{Cl}_{2}$ gas liberated is used to produce $\mathrm{HCl} . \mathrm{HCl}$ is reacted again with $\mathrm{Mg}(\mathrm{OH})_{2}$ to produce $\mathrm{MgCl}_{2}$

Reaction at the cathode (steel) :

$$
\mathrm{Mg}^{2+}(\mathrm{l})+2 \mathrm{e} \longrightarrow \mathrm{Mg}(\mathrm{l})
$$

Liquid magnesium formed is taken out from the cell. From this about $99.8 \%$ yield of Mg can be obtained. As the melting point of magnesium is about $650^{\circ} \mathrm{C}$, it exists as a liquid at $700^{\circ} \mathrm{C}$.

Figure 1.1 The cross sectional structure of the electro chemical cell producing magnesium
Strong and light weight metals are required for aircrafts and vehicles. Magnesium metal is very important for the production of alloys to have this kind of properties.

In this production, release of $\mathrm{CO}_{2}$ to the atmosphere is a disadvantage. $\mathrm{CO}_{2}$ is added to the atmosphere during the burning of limestone or dolomite and combustion of petroleum fuels to obtain a higher temperature associated with the electrolysing cell.

### 1.3 Production of caustic soda ( $\mathbf{N a O H}$ )

A pure concentrated solution of sodium chloride is called brine. NaOH is produced by electrolyzing a brine solution. As the by-products hydrogen gas and chloride gas are released at the cathode and the anode respectively.

$$
\begin{aligned}
& \mathrm{NaCl}(\mathrm{~s})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \xrightarrow{ } \mathrm{NaCl}(\mathrm{aq}) \\
& 2 \mathrm{NaCl}(\mathrm{~s})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \xrightarrow{\text { electrolysis }} 2 \mathrm{NaOH}(\mathrm{aq})+\mathrm{Cl}_{2}(\mathrm{~g})+\mathrm{H}_{2}(\mathrm{~g})
\end{aligned}
$$

When 2.25 metric tons are produced from a solution containing $50 \%(\mathrm{w} / \mathrm{w} \%)$ caustic soda, nearly I metric ton of chlorine gas and 30 kg hydrogen gas are produced. Though there is a consequence difference by mass like this, when the amounts of moles are considered, the amount of moles of chlorine and the amount of moles of hydrogen are approximately equal. In spite of the amounts of moles of chlorine and hydrogen formed are equal theoritically, the amounts of moles of chlorine and hydrogen that can be collected as gases are not equal. Since chlorine gas can slightly dissolve in the aqueous reaction medium, the amount of chlorine gas that can be collected in gaseous form is somewhat less than the amount of hydrogen.

The cells used to produce caustic soda by electrolysis are refered to as chlor-alkali cells. There are three types of cells.
a) Mercury cells
b) Diaphragm cells
c) Membrane cells

Earlier, production of NaOH was based on the mercury cell method. However, possibility of releasing mercury to the environment and contamination of NaOH with minute quantities of mercury are its main disadvantages. The basis of membrane cell and the diaphragm cell are almost identical. The major difference is that in the membrane cell, instead of a diaphragm, a membrane, permeable to $\mathrm{Na}^{+}$ions is used to separate the anode and the cathode. Compared to the membrane cell, in the diaphragm cell, the liquid level in the anode chamber is above the liquid level in the cathod chamber. Therefore, a hydrostatic pressure is exerted from the anode chamber solution to the cathode chamber solution across the asbestos diaphragm. This hydrostatic pressure affects the migration of $\mathrm{Na}^{+}$ions from the anode chamber to the cathode chamber. It also prevents the movement of $\mathrm{OH}^{-}$ions from the cathodic solution to the anode chamber solution. But in the membrane cell, the anode is separated from the cathode by a membrane that permits only the movement of positive ions. Higher purity of NaOH produced, lesser consumption of electricity and minimal impact on the environment are the advantages of the employment of membrane cells.

In this electrolytic process, electric potential used for electrolysis and the charge released from a unit area of the electrode surface in a unit time (current density) are important factors. This information is given in the following table.

Table 1.1 The factors included in associated with the cells are used for caustic soda production

|  | Mercury cell | Diaphragm cell | Membrane cell |
| :--- | ---: | ---: | ---: |
| Apply cell potential / V | 4.4 | 3.45 | 2.95 |
| Current density $/ \mathrm{A} \mathrm{cm}^{-2}$ | 1 | 0.2 | 0.4 |
| NaOH composition $(\mathrm{w} / \mathrm{w} \%)$ | 50 | 12 | 35 |

## Membrane cell method

The brine that is used in the membrane cell method should be very pure. Presence of $\mathrm{Mg}^{2+}, \mathrm{Ca}^{2+}$ and $\mathrm{SO}_{4}^{-2}$ ions in brine hinders the production process. Precipitations of these cations when the solution becomes basic disturbs the cell action. Lowering of the purity of
caustic soda because of the addition of these ions to the sodium hydroxide solution is also a disadvantage. Therefore, the concentration of these ionic impurities in brine that is used for the production should be at a very low level. Salt $(\mathrm{NaCl})$ extracted from sea water contains $\mathrm{Mg}^{2+}, \mathrm{Ca}^{2+}$ and $\mathrm{SO}_{4}{ }^{2-}$ ions. Hence, chemical treatment to remove impurity ions in brine prepared by this salt is a very important step. Sulfate ions can be precipitated and removed as $\mathrm{BaSO}_{4}$ by adding barium chloride in adequate quantities. $\mathrm{Mg}^{2+}$ and $\mathrm{Ca}^{2+}$ ions can be precipitated as $\mathrm{Mg}(\mathrm{OH})_{2}$ and $\mathrm{CaCO}_{3}$ by adding NaOH and $\mathrm{Na}_{2} \mathrm{CO}_{3}$ adequately.

$$
\begin{aligned}
& \mathrm{Mg}^{2+}(\mathrm{aq})+2 \mathrm{OH}^{-}(\mathrm{aq}) \longrightarrow \mathrm{Mg}\left(\mathrm{OH}_{12}(\mathrm{~s}) \downarrow\right. \\
& \mathrm{Ca}^{2+}(\mathrm{aq})+\mathrm{CO}_{3}^{2-}(\mathrm{aq}) \longrightarrow \mathrm{CaCO}_{3}(\mathrm{~s}) \downarrow \\
& \mathrm{Ba}^{2+}(\mathrm{aq})+\mathrm{SO}_{4}^{2-}(\mathrm{aq}) \longrightarrow \mathrm{BaSO}_{4}(\mathrm{~s}) \downarrow
\end{aligned}
$$

Inserting the concentrated salt solution (brine solution)

Figure 1.2 Membrane cell
At the beginning the solution in the anode chamber mainly contains $\mathrm{Na}^{+}$and $\mathrm{Cl}^{-}$ions and very small amounts of $\mathrm{H}^{+}$and $\mathrm{OH}^{-}$ions formed by the dissociation of water. The standard electrode potential required to oxidize $\mathrm{OH}^{-}$ions at the anode to give $\mathrm{O}_{2}$ is 0.4 V whereas the standard electrode potential for oxidizing $\mathrm{Cl}^{-}$ions at the anode to liberate $\mathrm{Cl}_{2}$ gas is 1.36 V . Hence, there is a possibility of liberating $\mathrm{O}_{2}$ in addition to $\mathrm{Cl}_{2}$. Several precautions have been taken to minimize releasing oxygen.

$$
\begin{aligned}
& 4 \mathrm{OH}^{-}(\mathrm{aq}) \longrightarrow \mathrm{O}_{2}(\mathrm{~g})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})+4 \mathrm{e} \\
& 2 \mathrm{Cl}^{-}(\mathrm{aq}) \longrightarrow \mathrm{Cl}_{2}(\mathrm{~g})+2 \mathrm{e}
\end{aligned}
$$

NaCl concentration in the brine used to produce caustic soda is relatively high. In a situation where the $\mathrm{OH}^{-}$concentration is very low and the $\mathrm{Cl}^{-}$concentration is very high, the probability of forming an oxygen molecule and two water molecules by combining four $\mathrm{OH}^{-}$ions on the electrode is relatively low. Since there is a relatively higher concentration
of $\mathrm{Cl}^{-}$ions in the anode chamber solution, the ability of forming $\mathrm{Cl}_{2}$ gas by the oxidation of $\mathrm{Cl}^{-}$ions is relatively greater.

With the electrolysis when the $\mathrm{Cl}^{-}$ion concentration decreases, there is a chance for the oxidation of $\mathrm{OH}^{-}$ions liberating $\mathrm{O}_{2}$. Because of this, a concentrated salt solution is continuously pumped into the anodic chamber and anodic chamber solution is continuously removed. Though the $\mathrm{Cl}^{-}$ion concentration in the system decreases, $\mathrm{Na}^{+}$ ion concentration does not decrease. When the entire cell is considered, maintenance of electric neutrality in the system is a fundamental feature, so, when $\mathrm{Cl}^{-}$ions are given off from the anodic chamber as $\mathrm{Cl}_{2}$ gas, either another negative ion should come into the anodic chamber solution or $\mathrm{Na}^{+}$ions should migrate into the cathodic chamber solution. Reduction takes place in the cathodic chamber. $\mathrm{H}^{+}$ion is more easily reduced than the aqueous $\mathrm{Na}^{+}$ion. At the beginning the medium in the cathodic chamber has no sodium chloride, so its main component is water. Since $\mathrm{H}^{+}$ions resulted by the dissociation of water molecules are continuously reduced, the equilibrium maintained by the reversible dissociation of water molecules drops. Since water molecules continuously dissociate with the removal of $\mathrm{H}^{+}$ions formed by the dissociation of water as $\mathrm{H}_{2}$ molecules, $\mathrm{OH}^{-}$ ion concentration in the cathodic chamber increases. When electrolysis is carried out continuously, $\mathrm{OH}^{-}$ion concentration in the cathodic chamber rises with time.

The equilibrium brought about by the dissociation of water molecules can be shown by equation (1)

$$
\begin{equation*}
\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \rightleftharpoons \mathrm{H}^{+}(\mathrm{aq})+\mathrm{OH}^{-}(\mathrm{aq}) \tag{1}
\end{equation*}
$$

The situation where the equilibrium is lost due to reduction of $\mathrm{H}^{+}$ions to $\mathrm{H}_{2}$ molecules is represented by equation (2)

$$
\begin{equation*}
\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow \mathrm{H}^{+}(\mathrm{aq})+\mathrm{OH}^{-}(\mathrm{aq}) . \tag{2}
\end{equation*}
$$

In the cathodic chamber $\mathrm{H}^{+}$ions get reduced to $\mathrm{H}_{2}$ molecules at a rate equal to the rate of oxidation of $\mathrm{Cl}^{-}$ions to $\mathrm{Cl}_{2}$ molecules in the anodic chamber. Because of this, the rate in which, water in the cathodic chamber continuously dissociates generating $\mathrm{OH}^{-}$ions is equal to the rate of decreasing of $\mathrm{Cl}^{-}$ions in the anodic chamber solution. Thus, the entire system is electrically neutral.

Along with the electrolysis, in a membrane cell, though the concentration of $\mathrm{Cl}^{-}$ions in the anode chamber decreases, $\mathrm{Na}^{+}$ion concentration does not decrease. Meanwhile, in the cathodic chamber $\mathrm{OH}^{-}$ion concentration increases because of the reduction of $\mathrm{H}^{+}$ ions formed by the dissociation of water. This develops a potential difference across
the membrane. If $\mathrm{OH}^{-}$ions in the cathodic chamber pass into the anode chamber, they react with chlorine in it. But, in the case of a membrane cell, $\mathrm{OH}^{-}$ions are not capable to migrate across the membrane, so this reation does not occur in the cathodic chamber solution.

In the membrane cell, the anodic and cathodic compartments are separated by a membrane permeable to positive ions $\left(\mathrm{Na}^{+}\right)$. This membrane has very tiny pores and negative ions are bound to the borders of these pores. The negative electric fields in the space around the pores attract positive ions towards the pores and repel negative ions. While water is continuously added to the cathodic chamber by an inlet tube while the solution containing NaOH is removed by an outlet.

Anode is made of titanium and cathode is made of nickel. Possibility to carry out the NaOH production process continuously is a special feature. Brine with concentration $26 \%$ is continuously pumped into the anodic chamber and as shown of the flow chart the concentration in the solution removed from the anodic solution has dropped up to $24 \%$. In the anodic chamber, when the generation of $\mathrm{Cl}_{2}$ by the oxidization of $\mathrm{Cl}^{-}$ions, $\mathrm{H}_{2}$ are formed by the reduction of $\mathrm{H}^{+}$ions in the cathodic chamber. Comparing to the increasing of the $\mathrm{OH}^{-}$ion concentration in the cathodic chamber, $\mathrm{Na}^{+}$ions existing in the anodic chamber move to the cathodic chamber. Therefore, a concentration of sodium hydroxide builds up in the cathodic chamber. With the movement of $\mathrm{Na}^{+}$ions, an electrical neutrality is brought about in each chamber. These process continuously occur during electrolysis.

The $\mathrm{Cl}^{-}$ions in the anodic chamber do not move into the cathodic chamber through the membrane. Hence, NaCl does not get mixed up as an impurity with NaOH .

Anodic reaction (Positive terminal)

$$
2 \mathrm{Cl}^{-}(\mathrm{aq}) \longrightarrow \mathrm{Cl}_{2}(\mathrm{~g})+2 \mathrm{e}
$$

Cathodic reaction (Negative terminal)

$$
2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})+2 \mathrm{e} \longrightarrow 2 \mathrm{OH}^{-}(\mathrm{aq})+\mathrm{H}_{2}(\mathrm{~g})
$$

Overall reaction

$$
2 \mathrm{NaCl}(\mathrm{aq})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow 2 \mathrm{NaOH}(\mathrm{aq})+\mathrm{Cl}_{2}(\mathrm{~g})+\mathrm{H}_{2}(\mathrm{~g})
$$

The flow chart for the production of NaOH by the membrane cell method.

## Uses of NaOH and by-products

Uses of NaOH

1. Production of soap
2. Production of paper, artificial silk and dyes
3. Using as a strong base
4. Precipitation of heavy metal as their hydroxides in waste water treatment.

Uses of chlorine

1. Bleaching textiles, woods and paper pulp
2. Purifying the drinking water
3. Production of HC 1
4. Production of chlorinated rubber, insecticides, dyes and medicine
5. Production of vinyl chloride required to produce polymers like PVC

Uses of hydrogen

1. Manufacture of HCl
2. Production of $\mathrm{NH}_{3}$
3. Production of margarine by hydrogenation of vegetable oil
4. Using as a fuel

### 1.4 Production of soap

During the manufacting of soap chemically, triglycerides are subject to a hydrolysis reaction with caustic soda (saponification) forming glycerol and sodium salts of long chain carboxylic acids. These salts are known as soap. A soap molecule comprises a hydrophobic tail made of carbon and hydrogen atoms and a site with a hydrophilic head, The hydrophilic head contains $\mathrm{Na}^{+}$or $\mathrm{K}^{+}$ion and the - $\mathrm{COO}^{-}$ionic group.
Animal fat or plant oil is a one raw meterial for the production of soap. The other raw meterial is NaOH or KOH .

Figure 1.3 Hydrophobic tail and hydrophilic head in a soap molecule

Soap is manufactured by two processes, hot process and the cold process. In the cold process, soap and glycerol are not separated. Glycerol is deposited in soap. Here only the hot porcess and its main 4 steps are considered

1. Saponification
2. Removal of the by-product, glycerin
3. Purification
4. Finishing

The number of carbon atoms in a soap molecule varies as $12,14,16$ and 18 . In coconut oil, lauric acid, myristic acid, stearic acid and oleic acid are bound by ester bonds in the triglycerides. The amount of long chain carboxylic acids (fatty acids) present in the form of triglycerides is indicated as a percentage. In addition to this, a small amount of fatty acids occurs as free fatty acids without forming ester bonds. In coconut oil $44-52 \%$ of Lauric acid prercent. The number of carbon atoms in it is 12.11 atoms out of them are in the hydrophobic tail. The percentage of myristic acid in coconut oil is $14 \%$ and it contains 14 carbon atoms. The percentages of parmitic acid ( 16 carbon atoms) and stearic acid (18 carbon atoms) in it are $8 \%$ and $3 \%$ respectively. Oleic acid has 18 carbon atoms and a double bond and its percentage in coconut oil is in the range of $5-8 \%$. Soap produced using coconut oil is a mixture of sodium salts of these acids.

To remove the pigments and impurities in oil, it is sent over a special type of clay referred to as activated fuller earth. It's temperature is maintained at about $90^{\circ} \mathrm{C}$. After removing the clay particles in oil, it is used to make soap. Soap production can be conducted either as a continuous process or a Batch Process.

Batch Process is the traditional method. In it all the amounts of raw materials are added together to the reaction chamber and allowed to react. Afterwards the products are separated. In the continuous process, reactants are continuously supplied to the reaction chamber and products are continuously removed.

## 1. Saponification

Here, purified vegetable oil (coconut oil) is mixed with a solution of aqueous NaOH and heated. The purified vegetable oil (e.g. coconut oil) and the caustic soda $(\mathrm{NaOH})$ solution or the caustic potash $(\mathrm{KOH})$ solution are pumped into the reaction chamber. Dissolving of caustic soda in water is exothermic. Therefore dissolving of caustic soda in water is done as a separated process.

Oil and aqueous sodium hydroxide are two immiscible phases. Glycerin and soap are formed as a result of the saponification reaction taking place at the interface of these two layers. Since NaOH is neutralized here, heat is produced. The temperature of the reaction mixture is maintained at $70^{\circ} \mathrm{C}$ and the mixture is mixed well. Oil divides into tiny droplets and increases the surface area. Therefore the reaction occurs uniformly throughout the entire volume of reaction mixture.

The saponification reaction can be written as follows.

## 2. Removal of glycerin

In the aqueous phase obtained after saponification, basicity has dropped. Glycerin and a certain amount of soap have dissolved in the aqueous phase. Soap molecules dissolved in the aqueous phase are ionized and maintain an equilibrium as follows. To decrease the solubility of soap in the aqueous phase NaCl (brine) is added. As the $\mathrm{Na}^{+}$ion concentration is high, the above equilibrium shifts to the left and the soap molecules separate from the aqueous phase. Glycerin dissolves in the salt solution. Density of the aqueous phase increases due to the addition of NaCl . After separating impure soap from the aqueous phase, the aqueous phase containing glycerin is pumped out.

$$
\text { Water }+\mathrm{RCOO} \stackrel{-}{\underset{\text { Wa }}{ }} \stackrel{(\mathrm{s})}{\stackrel{\text { When increasing } \mathrm{Na}^{+} \text {ion concentration }}{\rightleftharpoons} \mathrm{RCOO}^{-}(\mathrm{aq})+\mathrm{Na}^{+}(\mathrm{aq})}
$$

Pumping of crude soap is easy because the temperature is $70^{\circ} \mathrm{C}$ and crude soap contains a considerable amount of wetness (water). The aqueous salt solution removed from the reaction chamber contains glycerin. Thus, it is a good source to obtain glycerin. Adequate sodium chloride is added again to the solution obtained after removing glycerin and recycled. This salt solution is used to remove glycerin in impure soap. In this salt
solution, though glycerin dissolves, soap does not dissolve. Here, mixing soap well with the salt solution is very important. By this crude soap can be purified to a certain extent by removing glycerin remaining it. Then, the salt solution containing glycerin and soap partially purified and separated.

## 3. Purification

Water and NaCl salt are present in the soap which is purified upto a certain extent by removing glycerine. Wet soap with salt is centrifuged. Then the aqueous salt solution separates from soap. The NaCl content in soap decreases to $0.5 \%(\mathrm{w} / \mathrm{w})$.

Presence of caustic soda in soap is harmful to the user. Soap with high caustic soda content can severely damage the skin and tender tissues in eyes. Therefore citric acid, phosphoric acid or free fatty acids associated with coconut oil are added to neutralize sodium hydroxide which may be present even in minute quantities in soap.

## 4. Finishing

It is essential to remove water in soap after removing salts. To reduce the water content in soap to $12 \%(\mathrm{w} / \mathrm{w})$ soap heated to about $120^{\circ} \mathrm{C}$ is sprayed into a low pressure zone in the form of small droplets. As heat is abosorbed for the vaporization of water, the temperature of the droplets decreases. While water vapour is removed, soap settles down in the low pressure vessel. Dry soap is then separated. Finished soap is made by mixing fillers, colouring and perfumes and moulded into required shapes.

## TFM value of soap

TFM (Total Fatty Matter) means the total fatty matter presents in soap. It is the percentage of RCOONa (soap) present in a cake of soap. The TFM value of a cake of washing soap is about $54-56 \%$ and the rest is fillers, colouring and substances which promote the cleaning action and colouring.

A disadventage of soap is not dissolving and not lathering in hard water. Reason for this is, reaction of soap molecules with cations caused for the hardness and get precipitated.

$$
\begin{aligned}
& \mathrm{RCOO}^{-} \mathrm{Na}^{+}+\mathrm{M}^{2+} \longrightarrow(\mathrm{RCOO})_{2} \mathrm{M}+2 \mathrm{Na}^{+} \\
& \mathrm{M}=\mathrm{Ca}^{2+}, \mathrm{Mg}^{2+}, \mathrm{Fe}^{2+} \text { etc }
\end{aligned}
$$

Detergents do not precipitate in hard water. The main ingredients of artificial detergents is sodium alkylbenzenesulphonate.

## Cleaning action of soap

Dirt is a mixture of dust particles and organic compounds gathered around on a layer of oil. As the surface tension of water is high dirt doesn't remove only with water. Soap lowers the surface tension of water and improves its cleaning action.

Figure 1.4 Cleaning action of soap
Since soap molecules form micella with oily droplets as shown above, dirt gets removed.

### 1.5 Production of $\mathrm{Na}_{2} \mathrm{CO}_{3}$ (Solvey process/ Ammonia - soda process)

Sodium carbonate is a raw material required for a number of chemical industries. Therefore $\mathrm{Na}_{2} \mathrm{CO}_{3}$ production is a major chemical industry in the world. Presently about 20 million metric tons of $\mathrm{Na}_{2} \mathrm{CO}_{3}$ are annually produced in the world.

The main chemical reactions involved in the production of $\mathrm{Na}_{2} \mathrm{CO}_{3}$ are given below.

$$
\begin{aligned}
& \mathrm{NH}_{3}+\mathrm{H}_{2} \mathrm{O} \rightleftharpoons \mathrm{NH}_{4} \mathrm{OH} \\
& \mathrm{NH}_{4} \mathrm{OH}+\mathrm{CO}_{2} \longrightarrow \mathrm{NH}_{4} \mathrm{HCO}_{3} \\
& \mathrm{NaCl}+\mathrm{NH}_{4} \mathrm{HCO}_{3} \longrightarrow \mathrm{NaHCO}_{3}+\mathrm{NH}_{4} \mathrm{Cl} \\
& 2 \mathrm{NaHCO}_{3} \xrightarrow{\Delta} \mathrm{Na}_{2} \mathrm{CO}_{3}+\mathrm{CO}_{2}+\mathrm{H}_{2} \mathrm{O}
\end{aligned}
$$

$\mathrm{NH}_{3}$ essential for the production of $\mathrm{Na}_{2} \mathrm{CO}_{3}$ is obtained by the Haber process. $\mathrm{CO}_{2}$ is produced by the thermal decomposition of limestone. The other main raw material is purified concentrated NaCl solution by removing $\mathrm{Ca}^{2+}, \mathrm{Mg}^{2+}$ and $\mathrm{SO}_{4}{ }^{2-}$ ions. This is refered to as brine.

$$
\mathrm{CaCO}_{3} \rightleftharpoons \stackrel{\Delta}{\rightleftharpoons} \mathrm{CaO}+\mathrm{CO}_{2}
$$

The basic steps of the process occur in specially setup towers for the production of $\mathrm{Na}_{2} \mathrm{CO}_{3}$, can be briefly stated as follows.

## Step 1 - Ammonification

First the brine solution is introduced from the top of the tower and ammonia gas is introduced from the bottom of the tower. Mixing reactants efficiently by sending the reactants in opposite directions is referred to as the countercurrent principle. Ammonification of brine is an exothermic process. Hence, if the temperature of brine increases, efficiency of dissolving ammonia decreases. It is important to maintain a low temperature in the tower by removing the heat in the tower through heat exchange.

Figure 1.5 Ammonification tower

## Step 2 - Carbonation

The brine solution saturated with ammonia is introduced from the top of the second tower while $\mathrm{CO}_{2}$ is introduced from the bottom. Here, the reactants efficiently mix under the counter current method. Ammonified brine is a basic medium. $\mathrm{CO}_{2}$ is an acidic gas. Dissolving it in water is exothermic. Hence formation of $\mathrm{NH}_{4} \mathrm{HCO}_{3}$ by reacting aqueous $\mathrm{CO}_{2}$ with $\mathrm{NH}_{4} \mathrm{OH}$ is also exothermic. For this also keeping the second tower cool is very important.

Figure 1.6 Carbonation tower
$\mathrm{NH}_{3}$ is readily soluble in water but the solubility of $\mathrm{CO}_{2}$ gas in water is relatively low. The concentration of $\mathrm{HCO}_{3}^{-}$ions formed by the dissolution of carbon dioxide in water is also very low. As ammonification proceedes carbonation, $\mathrm{CO}_{2}$ gas is absorbed well into the basic $\mathrm{NH}_{3}(\mathrm{aq})$ solution. This produces a high concentration of $\mathrm{HCO}_{3}^{-}$ions.

## Step 3 - Seperation of $\mathrm{NaHCO}_{3}$

As ammonification brine solution is carbonated, the concentration of $\mathrm{NH}_{4} \mathrm{HCO}_{3}$, in the solution is increased. Since this brine has a high concentration of $\mathrm{Na}^{+}$ions, $\mathrm{NaHCO}_{3}$ Crystallizes and separates out from the solution when the concentrations of $\mathrm{Na}^{+}$and $\mathrm{HCO}_{3}^{-}$ions exceed the saturation limit of $\mathrm{NaHCO}_{3}$. The overall reaction can be indicated as,

$$
\mathrm{Na}^{+}(\mathrm{aq})+\mathrm{HCO}_{3}^{-}(\mathrm{aq}) \longrightarrow \mathrm{NaHCO}_{3}(\mathrm{~s})
$$

The solid $\mathrm{NaHCO}_{3}$ that forms is removed from the solution.
The overall reaction of forming $\mathrm{NaHCO}_{3}$ can be written as follows.
Accordingly the raw materials essential for the production of $\mathrm{NaHCO}_{3}$ in theoritical point through Solvey process are $\mathrm{NH}_{3}, \mathrm{CO}_{2}, \mathrm{NaCl}$ and $\mathrm{H}_{2} \mathrm{O}$.

$$
\mathrm{NH}_{3}(\mathrm{~g})+\mathrm{CO}_{2}(\mathrm{~g})+\mathrm{NaCl}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow \mathrm{NaHCO}_{3}(\mathrm{~s})+\mathrm{NH}_{4} \mathrm{Cl}(\mathrm{aq})
$$

## Step 4 - Obtaining $\mathrm{Na}_{2} \mathrm{CO}_{3}$ by heating $\mathrm{NaHCO}_{3}$

Anhydrous $\mathrm{Na}_{2} \mathrm{CO}_{3}$ is obtained by heating $\mathrm{NaHCO}_{3}$ which is separated. $\mathrm{CO}_{2}$ gas formed is sent back to the carbonation tower.

$$
2 \mathrm{NaHCO}_{3}(\mathrm{~s}) \longrightarrow \mathrm{Na}_{2} \mathrm{CO}_{3}(\mathrm{~s})+\mathrm{CO}_{2}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

$\mathrm{NH}_{4} \mathrm{Cl}$ which is a by-product of this process is used to regenerate $\mathrm{NH}_{3}$ as follows. For this $\mathrm{NH}_{4} \mathrm{Cl}$ solution is reacted with CaO oxide obtained by the decomposition of limestone.

$$
\mathrm{CaO}(\mathrm{~s})+2 \mathrm{NH}_{4} \mathrm{Cl}(\mathrm{aq}) \longrightarrow 2 \mathrm{NH}_{3}(\mathrm{~g})+\mathrm{CaCl}_{2}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

$\mathrm{NH}_{3}$ formed is passed to the ammonifying tower. Accordingly the overall theroitical reaction for the entire process is as follows. However by mixing solid $\mathrm{CaCO}_{3}$ and aqueous $\mathrm{NaCl}, \mathrm{Na}_{2} \mathrm{CO}_{3}$ cannot be prepared.

$$
\mathrm{CaCO}_{3}(\mathrm{~s})+2 \mathrm{NaCl}(\mathrm{aq}) \longrightarrow \mathrm{CaCl}_{2}(\mathrm{aq})+\mathrm{Na}_{2} \mathrm{CO}_{3}(\mathrm{~s})
$$

The final by-product of this process is $\mathrm{CaCl}_{2}$. It can also be used for other industries.
Due to following reasons Solvey process is economical profitable.

1) NaCl and $\mathrm{CaCO}_{3}$ can be obtained easily and with low cost.
2) $\mathrm{NH}_{3}$ is not consumed and can be used again and again by re-cycling.
3) A part of $\mathrm{CO}_{2}$ can be re-used.

Solubility of $\mathrm{KHCO}_{3}$ is higher than the solubility of $\mathrm{NaHCO}_{3}$. So $\mathrm{KHCO}_{3}$ is not precipitated in the tower. Therefore above method cannot be used to make $\mathrm{KHCO}_{3}$.

## Uses of $\mathrm{Na}_{2} \mathrm{CO}_{3}$

1) Removal of hardness of water
2) Addition to improve cleaning action when producing soap and detergents.
3) Using as washing soda
4) Mixing to the wood pulp in paper industry
5) Production of glass

### 1.6 Production of ammonia (Haber-Bosch process)

In modern context, manufacture of ammonia is mainly needed for the production of artificial fertilizers. At present the world population is nearly 7.3 billion and it has been estimated that it will increase to about 9 billion by 2050 . With the increasing of the population, production of food is a necessity. Production of fertilizer is considered as an important field of chemical manufacture in this regard.

Of the total ammonia production $83 \%$ is used to produce fertilizer. Specially $80 \%$ of the total ammonia production is used to manufacture urea.
The chemical reaction related to the production of ammonia is given below.
$\underset{1}{\mathrm{~N}_{2}(\mathrm{~g})+3 \mathrm{H}_{2}(\mathrm{~g}) \longrightarrow} \longrightarrow 2 \mathrm{NH}_{3}(\mathrm{~g})+$ heat

## Raw materials required to produce ammonia

$\mathrm{N}_{2}$ gas and $\mathrm{H}_{2}$ gas are the main raw materials. $\mathrm{N}_{2}$ gas is separated by fractional distillation of liquefied atmospheric air. Therefore $\mathrm{N}_{2}$ gas has a production cost.
Hydrogen gas is obtained by cracking hydrocarbons (naphtha) or using methane, which is the main component of natural gas.

Extra knowledge
Natural gas is used as a fossil fuel to generate power. Natural gas occurs in large quantities as underground ores in the Earth. Production of $\mathrm{H}_{2}$ from natural gas is known as Steam-Methane-Reforming (SMR). A small quantities of $\mathrm{H}_{2} \mathrm{~S}$ is present in natural gas; $\mathrm{H}_{2} \mathrm{~S}$ disturbs Nickel catalytic process. Furthermore $\mathrm{H}_{2}$ is formed by a catalytic reaction after removing $\mathrm{H}_{2} \mathrm{~S}$ in the natural gas.
The reaction related with removals of $\mathrm{H}_{2} \mathrm{~S}$

$$
\mathrm{H}_{2} \mathrm{~S}(\mathrm{~g})+\mathrm{ZnO}(\mathrm{~s}) \rightleftharpoons \mathrm{ZnS}(\mathrm{~s})+\mathrm{H}_{2} \mathrm{O}(\mathrm{~g})
$$

The first step of the SMR process is reacting methane and water vapour at $700{ }^{\circ} \mathrm{C}$ $800{ }^{\circ} \mathrm{C}$ to produce CO and $\mathrm{H}_{2}$. This is an endothermic reaction.

$$
\begin{equation*}
\mathrm{CH}_{4}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{O}(\mathrm{~g}) \longrightarrow \mathrm{CO}(\mathrm{~g})+3 \mathrm{H}_{2}(\mathrm{~g})+206 \mathrm{~kJ} \mathrm{~mol}^{-1} \tag{1}
\end{equation*}
$$

$\qquad$
During the second step this gaseous mixture is further reacted with water vapour. Here, CO is converted to $\mathrm{CO}_{2}$. This is an exothermic reaction.

$$
\begin{equation*}
\mathrm{CO}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{O}(\mathrm{~g}) \rightleftharpoons \mathrm{CO}_{2}(\mathrm{~g})+\mathrm{H}_{2}(\mathrm{~g}) \quad-41 \mathrm{~kJ} \mathrm{~mol}^{-1} \tag{2}
\end{equation*}
$$

In addition to this, there is a possibility for the following reaction to occur.

$$
\begin{equation*}
\mathrm{CH}_{4}(\mathrm{~g})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{~g}) \longrightarrow 4 \mathrm{H}_{2}(\mathrm{~g})+\mathrm{CO}_{2}(\mathrm{~g}) \tag{3}
\end{equation*}
$$

The yield of $\mathrm{H}_{2}$ can be increased by maintaining more water vapuour and shifting the total reaction to the right.

To have some understanding of the thermodynamic nature of the SMR, the relationship $\Delta \mathrm{G}=\Delta \mathrm{H}-\mathrm{T} \Delta \mathrm{S}$ can be used.

According to the above thermodynamic relationship the exothermic second reaction is spontaneous even at low temperature. Since the number of gaseous molecules does not change, pressure has no effect. Further the effect of $T \Delta S$ on $\Delta G$ is almost nil.

First and third endothermic reactions occur relatively at higher temperatures. The entropy increases because the number of gaseous molecules increases to the forward
direction. So, with increase in temperature, the positive value of $\mathrm{T} \Delta \mathrm{S}$ increases. Therefore according to $\Delta \mathrm{G}=\Delta \mathrm{H}-\mathrm{T} \Delta \mathrm{S}$, in reactions 1 and $3 \Delta \mathrm{G}$ becomes more negative at higher temperatures. Reaction 1 is alllowed to occur at a high temperature $\left(1000-1800^{\circ} \mathrm{C}\right)$. There even reaction 3 may occur. In order to reduce the CO concentration and increase the yield of $\mathrm{H}_{2}$, the second reaction is allowed to occur at relatively at low temperatures $\left(200-400{ }^{\circ} \mathrm{C}\right)$. By adding water vapour to the hot gaseous mixture of CO and $\mathrm{H}_{2}$ its temperature can be lowered $\left(200-400^{\circ} \mathrm{C}\right)$. As the second reaction is exothermic, the heat generated by the second reaction is used to obtain the higher temperature suitable for the first reaction.

In United States, about $60 \%$ of natural gas production is used for the production of ammonia gas. Hydrogen gas can also be obtained by cracking naphtha $\left(\mathrm{C}_{6} \mathrm{H}_{14}\right)$. It also release $\mathrm{CO}_{2}$ to the atmosphere. The relevant reactions that occur are as follows.

$$
\begin{aligned}
& \mathrm{C}_{6} \mathrm{H}_{14}(\mathrm{~g})+6 \mathrm{H}_{2} \mathrm{O}(\mathrm{~g}) \longrightarrow 6 \mathrm{CO}(\mathrm{~g})+13 \mathrm{H}_{2}(\mathrm{~g}) \\
& \mathrm{CO}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{O}(\mathrm{~g}) \longrightarrow \mathrm{CO}_{2}(\mathrm{~g})+\mathrm{H}_{2}(\mathrm{~g})
\end{aligned}
$$

Production of $\mathrm{NH}_{3}$ from hydrogen and nitrogen gases is an exothermic reaction and it is reversible. But, under normal temperature and pressure this reaction hardly happens. The reason is the activation energy is relatively high.

## Producing $\mathrm{NH}_{3}$ by $\mathbf{H}_{2}$ and $\mathbf{N}_{2}$

Industrially, ammonia is manufacture by the Haber-Bosh process. The optimum industrial conditions employed for the process are a temperature in the range $450-500{ }^{\circ} \mathrm{C}$, a pressure of 250-300 atm, iron catalyst and $\mathrm{K}_{2} \mathrm{O}$ and $\mathrm{Al}_{2} \mathrm{O}_{3}$ as catalystic promoters.

$$
\mathrm{N}_{2}(\mathrm{~g})+3 \mathrm{H}_{2}(\mathrm{~g}) \stackrel{250-300 \mathrm{~atm}}{\stackrel{250-500^{\circ} \mathrm{C}}{\rightleftharpoons}} 2 \mathrm{NH}_{3}(\mathrm{~g})+\text { heat }
$$

The compressed mixture of reactant gases pass over the surface of the catalyst and gets converted to $\mathrm{NH}_{3}$. Since the reaction is reversible the gaseous mixture passing the catalyst surface contains unreacted $\mathrm{H}_{2}$ and $\mathrm{N}_{2}$ gas in addition to $\mathrm{NH}_{3}$. Therefore $\mathrm{NH}_{3}$ gas should be seperated from this mixture. When the mixture is cooled upto $-33.34{ }^{\circ} \mathrm{C}$, $\mathrm{NH}_{3}$ gas liquefies. The boiling points of nitrogen and hydrogen gases are $-195.8{ }^{\circ} \mathrm{C}$ and -252.9 ${ }^{0} \mathrm{C}$ respectively. So by cooling this mixture only ammonia can be liquefied and the mixture of $\mathrm{H}_{2}$ and $\mathrm{N}_{2}$ can be separated from the reaction mixture. The gaseous mixture containing $\mathrm{H}_{2}, \mathrm{~N}_{2}$ and $\mathrm{NH}_{3}$ under high pressure can be cooled by decreasing the pressure suddenly in another chamber. Then $\mathrm{NH}_{3}$ liquefies. Remaining $\mathrm{H}_{2}$ and $\mathrm{N}_{2}$ gases are then pumped back into the reaction chamber. Equal amounts of $\mathrm{H}_{2}$ and $\mathrm{N}_{2}$ that have been used to make $\mathrm{NH}_{3}$ are then freshly added.

This process can be depicted by Figure 1.7 in a simplified way.

Figure 1.7 Process of ammonia production
After the removal of liquid ammonia, the gaseous mixture containing unreacted and newly added $\mathrm{N}_{2}$ and $\mathrm{H}_{2}$ gases (under a temperature of around $-33.34{ }^{\circ} \mathrm{C}$ ) is heated to $450-500{ }^{\circ} \mathrm{C}$. The heat energy required to have this temperature can be supplied by the combustion of fuel also. This releases $\mathrm{CO}_{2}$ to the atmosphere. In the Haber process $\mathrm{CO}_{2}$-is produced at the step in which hydrogen is produced and also during the burning of fuel to gain high temperature. Due to the overall process, $\mathrm{CO}_{2}$ which is a green house gas releases to atmosphere. Globally, when 1 tonne of ammonia is produced by overall process, about 2.9 tonnes of $\mathrm{CO}_{2}$ is released to the atmosphere. Compared to the releasing of $\mathrm{CO}_{2}$ to atmosphere by other processes, approximately $1.4 \%$ of it, is by ammonia production.

In ammonia production $\mathrm{N}_{2}$ and $\mathrm{H}_{2}$ are mixed according to their stoichiometric ratio (1:3). Since some cost has to be borne to produce nitrogen gas and hydrogen gas they are not mixed beyond their stoichiometric ratio and this prevents wastage of raw materials. Further if one gas is used in excess it would be adsorbed by the surface of the catalyst covering the surface completely. Coverage of catalyst surface by one gas reduces the chances for the reaction to occur. Both the gases need to be absorbed to the catalyst surface. Use of the catalyst decreases the time to reach the equilibrium. Based on all the factors, $\mathrm{N}_{2}$ and $\mathrm{H}_{2}$ gases are mixed in the optimal ratio of 1:3.

The reaction is exothermic, so it's $\Delta \mathrm{H}$ is negative. When the reaction proceeds, entropy decreases because the number of molecules decreases. Hence $\Delta \mathrm{S}$ of the reaction is negative. Thus $\mathrm{T} \Delta \mathrm{S}$ is negative and $-\mathrm{T} \Delta \mathrm{S}$ is positive. Therefore with the increase in temperature $\Delta \mathrm{G}$ changes from negative to positive. The fact that high temperatures do not favour the forward reaction can also be explained by Le Chatelier's principle.

On increasing the temperature the spontaneous nature of the reaction decreases. Thermodynamically, when the spontaneity decreases, the yield decreases. To increase the yield, the temperature should be decreased. But when the temperature is decreased the rate of the reaction decreases and the efficiency of the entire process declines. A temperature of $450-500{ }^{\circ} \mathrm{C}$ is used to maintain an optimum efficiency. The $\mathrm{NH}_{3}$ yield obtained under these conditions is relatively low. Yet, the production process has been designed so that the unreacted $\mathrm{H}_{2}$ and $\mathrm{N}_{2}$ gases are brought into the catalytic cycles again and again. Despite the fact that the amount of $\mathrm{NH}_{3}$ yield by a single step is small, the process as a whole gains a high yield because it has been designed to carry out via number of catalytic cycles. According to Le Chatelier's principle, higher pressures favour the forward reaction. But the maintenance cost of the plants withstanding high pressures is high. Therefore at present, a pressure of $250-300 \mathrm{~atm}$ is used. Maintenance of reactant concentration at a high level and product concentration at a low level results in a higher yield of $\mathrm{NH}_{3}$. This can be explained by the Le Chatelier's Principle. This requirement is fulfilled by introducing $\mathrm{N}_{2}$ and $\mathrm{H}_{2}$ into the reaction chamber from time and removal of $\mathrm{NH}_{3}$ by cooling the gaseous mixture containing $\mathrm{NH}_{3}$ and liquefying the gas.

## Uses of ammonia

1. Production of nitric acid, fertilizers and nylon
2. Petroleum industry utilizes ammonia in neutralizing the acid constituents of crude oil
3. Used in water and waste water treatment, such as pH control, in solution form to regenerate weak anion exchange resins
4. Used as a refrigerant
5. Used in the rubber industry for the stabilization of natural and synthetic latex to prevent premature coagulation

### 1.7 Production of nitric acid (Ostwald method)

For this, ammonia gas, atmospheric air and water are used as raw materials. Nitrogen dioxide gas obtained by the reaction between ammonia and oxygen gas is reacted with water to produce nitric acid. The reaction involved are;

$$
\begin{aligned}
& 4 \mathrm{NH}_{3}(\mathrm{~g})+5 \mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 4 \mathrm{NO}(\mathrm{~g})+6 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})\left(-907 \mathrm{~kJ} \mathrm{~mol}^{-1}\right) \\
& \left.2 \mathrm{NO}_{(\mathrm{g})}\right)+\mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{NO}_{2}(\mathrm{~g})\left(-114 \mathrm{~kJ} \mathrm{~mol}^{-1}\right) \\
& 3 \mathrm{NO}_{2}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow 2 \mathrm{HNO}_{3}(\mathrm{aq})+\mathrm{NO}(\mathrm{~g}) \\
& \left.2 \mathrm{NO}_{(\mathrm{g})}\right)+\mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{NO}_{2}(\mathrm{~g}) \\
& 4 \mathrm{NO}_{2}(\mathrm{~g})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 4 \mathrm{HNO}_{3}(\mathrm{aq})
\end{aligned}
$$

Figure 1.8 simply illustrates this process.

Figure 1.8 Production of nitric acid
In the first chamber ammonia is oxidized in the presence of the catalyst. In the second chamber nitrogen monoxide gas (nitric oxide) is oxidized. Nitrogen dioxide gas is reacted with water in the third chamber.

Ammonia is oxidized using atmospheric air from which dust and water vapour have been removed. Ordinary air contains $78 \%$ nitrogen gas and $21 \%$ oxygen gas by volume. A volume of atmospheric air which contains the required amount of oxygen is pumped into the reaction chamber. For a unit volume of ammonia, 9-12 units of atmospheric air by volume are required. A high temperature range $\left(800-850{ }^{\circ} \mathrm{C}\right)$ is maintained. Under these conditions around $97 \%$ of NO gas can be obtained. If the ammonia concentration is high explosions may occur. Therefore maintaining the volumes of ammonia and atmospheric air in the correct proportion is important. When this gas mixture is passed through the $\mathrm{Pt} / \mathrm{Rh}$ catalyst under pressure it is converted to NO gas. This NO gas is cooled to $150^{\circ} \mathrm{C}$. When the temperature is $150^{\circ} \mathrm{C}$, further oxidation of NO to $\mathrm{NO}_{2}$ occurs in the oxidation chamber. In the absorption chamber $\mathrm{NO}_{2}$ gas is allowed to react with water conforming to the counter-current principle. The gaseous mixture containing oxygen and $\mathrm{NO}_{2}$ is pumped into the absorption chamber under a pressure of 5-10 atm. As the absorption chamber is packed with chemically inactive substances greater chance is offered for the reaction between water and $\mathrm{NO}_{2}$. Finally a yield of around $96 \%$ is obtained.

## Uses of nitric acid

1. Making fertilizer and explosives
2. Making nitrates essential for industries
$\mathrm{KNO}_{3}$ - to produce gun power
$\mathrm{AgNO}_{3}$ - photography
3. Making aqua regia
4. Cleaning surfaces when welding metals

### 1.8 Production of sulfuric acid (Contact process)

## Raw materials required to produce sulphuric acid

Sulphur or ores containing shlphur and water are used in this manufacture. When extracting the metals $\mathrm{Pb}, \mathrm{Cu}$ and Zn from ores containing $\mathrm{PbS}, \mathrm{CuS}$ and ZnS , sulphur dioxide is obtained as a by - product. This can also be used to produce $\mathrm{H}_{2} \mathrm{SO}_{4}$. Shlphur obtained as a by - product during petroleum refining or sulphur extracted from earth can also be used for this.

In the production of sulphuric acid, sulphur dioxide is made by burning sulphur or metal sulphides. Second step is the preparing of sulphur trioxide by reacting sulphur dioxide with atmospheric oxygen. Sulphuric acid is obtained by hydrolyzing pyrosulphuric acid $\left(\mathrm{H}_{2} \mathrm{~S}_{2} \mathrm{O}_{7}\right.$, oleum) made by reacting sulphur trioxide with concentrated sulphuric acid.

$$
\begin{aligned}
& \mathrm{S}(\mathrm{~s})+\mathrm{O}_{2}(\mathrm{~g}) \longrightarrow \mathrm{SO}_{2}(\mathrm{~g}) \\
& 2 \mathrm{SO}_{2}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \underset{\nabla_{2} \mathrm{O}_{5}(\mathrm{~s}) \text { catalyst }}{\text { atm, } 400^{\circ} \mathrm{C}} 2 \mathrm{SO}_{3}(\mathrm{~g})+\text { heat } \\
& \mathrm{SO}_{3}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{SO}_{4}(\mathrm{aq}) \longrightarrow \mathrm{H}_{2} \mathrm{~S}_{2} \mathrm{O}_{7}(\mathrm{aq}) \\
& \mathrm{H}_{2} \mathrm{~S}_{2} \mathrm{O}_{7}(\mathrm{aq})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow 2 \mathrm{H}_{2} \mathrm{SO}_{4}(\mathrm{aq})
\end{aligned}
$$

Production of sulphur dioxide by burning elemental sulphur is a separate process. In the school laboratory sulpher dioxide can easily be prepared by burning a piece of sulphur with the bunsen burner. But production of sulphur dioxide industrially is not that easy. First sulphur is heated to $140^{\circ} \mathrm{C}$ and melted. Liquid sulphur is filtered to remove various solid impurities in it.

Figure 1.9 Production process of sulphuric acid

Liquid sulphur and atmospheric air should be pumped into the furnace. Liquid sulphur is pumped in the form of very small droplets which burn easily. Combution of sulphur is exothermic. In the gaseous mixture obtained after burning, the composition of sulphur dioxide is maintained between $8-9 \%$.

The temperature around the burner is about $830{ }^{\circ} \mathrm{C}$. In the gasous mixture of sulphur dioxide, oxygen and nitrogen in the combusion chamber, various solid particles (ash) may be present. Removal of them is crucial because the particles of dust and ash setting on the surface of $\mathrm{V}_{2} \mathrm{O}_{5}$ catalyst retards the catalytic action. Therefore, first the gaseous mixture containing $\mathrm{SO}_{2}$ is purified. The reaction producing sulphur trioxide is reversible and exothermic. The molar ratio (or ratio by volume) between oxygen and sulphur dioxide is maintained at 1:1.

$$
2 \mathrm{SO}_{2}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \rightleftharpoons 2 \mathrm{SO}_{3}(\mathrm{~g})+\text { heat }
$$

For efficient progression of the reaction, an optimum temperature of $400-500{ }^{\circ} \mathrm{C}$ is maintained. The reaction itself generates heat. Thus, if the production plan was designed to react the whole amount of $\mathrm{SO}_{2}$ with $\mathrm{O}_{2}$ at once, a huge amount of heat would be liberated. This favours the backward reaction and reduces the yield. Hence the entire amount of $\mathrm{SO}_{2}$ is converted to $\mathrm{SO}_{3}$ in four steps. In every step the gaseous mixture is passed through the catalyst bed.

In order to increase the $\mathrm{SO}_{3}$ yield by shifting the above reversible reaction to the right, oxygen concentration can be increased by supplying atmospheric air. As atmospheric air is a cheap raw material, this does not increase the production cost. According to the stoichiometry the ratio of $\mathrm{SO}_{2}: \mathrm{O}_{2}$ is $2: 1$. The amount of oxygen required for one mole of $\mathrm{SO}_{2}$, is 0.5 . But during the production the molar ratio maintained as $1: 1$. So 0.5 moles of $\mathrm{O}_{2}$ is in excess for 1 mole of $\mathrm{SO}_{2}$. Though atmospheric air is cheap, maintaining a higher oxygen concentration above the required concentration, decreases the efficiency of the process. This is because of higher the oxygen concentration, more $\mathrm{O}_{2}$ molecules get adsorbed to the catalyst surface. This reduces the capacity of the catalyst to adsorb $\mathrm{SO}_{2}$ molecules there by decreasing the probability for the reaction to occur.

This reaction is exothermic. Therefore increase in the yield on cooling can be predicted from Le Chaterier's Principle. But the decrease in the rate of the reaction at low temperatures brings down the efficiency of the production process. Hence, it has been decided that the optimum temperature is $400-450^{\circ} \mathrm{C}$.

Le Chaterier's Principle predicts that with increasing pressure the reversible reaction tends to move in favour of the direction in which the number of molecules in the gas phase decreases. In this reaction, increase in pressure favours the forward reaction increasing the productivity of $\mathrm{SO}_{3}$. But in this particular reaction the yield is as higher as $99 \%$ even under 1 atm pressure. Therefore applying high pressures is unnecessary.

As this reaction is highly exothermic the production process is conducted in four steps managing heat exchange. This is illustrated in the following flow chart (Figure 1.10)

Figure 1.10 Main heat exchange steps in the production of sulfuric acid

The temperature of the gases entering the first chamber is around $690 \mathrm{~K}\left(417^{\circ} \mathrm{C}\right)$. When passing through the catalyst, the temperature rises to $890 \mathrm{~K}\left(617{ }^{\circ} \mathrm{C}\right)$ and about $70 \%$ of $\mathrm{SO}_{2}$ gets oxidized. The gases cooled to about $700 \mathrm{~K}\left(427^{\circ} \mathrm{C}\right)$ is passed through the second bed of catalyst. At this stage the amount of $\mathrm{SO}_{2}$ present is relatively low. For this reason the amount of $\mathrm{SO}_{3}$ formed is less than that formed in the first step and the amount of heat generated is also relatively low. The second heat exchanger cools the gaseous mixture whose temperature has risen to $770 \mathrm{~K}\left(497{ }^{\circ} \mathrm{C}\right)$ to $720 \mathrm{~K}\left(447{ }^{\circ} \mathrm{C}\right)$. By that time, a considerable amount of $\mathrm{SO}_{2}$ from its initial amount has reacted. After passing through catalyst bed in the third chamber $98 \%$ of $\mathrm{SO}_{2}$ of its initial amount turns into $\mathrm{SO}_{3}$.

Sulphuric acid is made by the $\mathrm{SO}_{3}$ obtained from the third step. Here also, $100 \%$ of $\mathrm{SO}_{3}$ is not converted to $\mathrm{H}_{2} \mathrm{SO}_{4}$. The gaseous mixture containing the remaining $\mathrm{SO}_{3}$ and the $\mathrm{SO}_{2}$ left due to reversibility is heated again and passed through the catalyst in the fourth chamber which converts it to $\mathrm{SO}_{3}$. This $\mathrm{SO}_{3}$ is also converted to $\mathrm{H}_{2} \mathrm{SO}_{4}$ again.

The reaction between $\mathrm{SO}_{3}$ and water is violent and highly exothermic. Therefore water vaporizes and a mist of sulphuric acid fumes is made. To avoid this $\mathrm{SO}_{3}$ gas is converted to $\mathrm{H}_{2} \mathrm{SO}_{4}$ via the steps described above. The absorption of $\mathrm{SO}_{3}$ is maximum in concentrated ( $98 \%$ ) sulphuric acid at $70{ }^{\circ} \mathrm{C}$. Therefore under those conditions $\mathrm{SO}_{3}$ is absorbed into concentrated sulphuric acid and $\mathrm{H}_{2} \mathrm{SO}_{4}$ is made by adding water to it.

Sulphur trioxide and concentrated sulphuric acid are reacted according to the counter current principle. This happens in absorption towers which are packed with ceramic materials. Because of the packing, sulphuric acid slowly trickles down the chamber from top to bottom and the surface area of liquid $\mathrm{H}_{2} \mathrm{SO}_{4}$ is increased. Sulphur trioxide moves up the chamber. Increased surface area of the acid coupled with its slow flow and the upward movement of $\mathrm{SO}_{3}$ gas make the absorption efficient. Here, $\mathrm{SO}_{3}$ reacts with $\mathrm{H}_{2} \mathrm{SO}_{4}$ giving oleum ( $\mathrm{H}_{2} \mathrm{~S}_{2} \mathrm{O}_{7}$ ). Concentrated sulphuric acid is made by adding water to oleum carefully.

## Uses of sulphuric acid

1. Production of phosphate fertilizers
2. Production of ammonium sulphate fertilizer
3. Production of artificial fibers including rayon and plastics
4. Production of detergents containing alkyl and aryl sulphonates
5. Production of dyes, explosives and medicines
6. Production of battery acid
7. Drying gases (e.g. $\mathrm{Cl}_{2}$ )

### 1.9 Production of titanium dioxide from rutile

Ilmenite and rutile are main minerals which contain titanium. The mineral in which titanium is present in abundance in the form of $\mathrm{TiO}_{2}$ is rutile. Ilmenite is a mixture of the two oxides $\mathrm{TiO}_{2}$ and FeO . When producing $\mathrm{TiO}_{2}$ using Ilmenite, first FeO in it is removed. This increases its $\mathrm{TiO}_{2}$ percentage. Removal of FeO from ilmenite is called sulphate process.

High purity $\mathrm{TiO}_{2}$ is produced from ilmenite in which the percentage of $\mathrm{TiO}_{2}$ is brought above $70 \%$ by removing FeO . High purity $\mathrm{TiO}_{2}$ can be produced starting from ilmenite purified until its $\mathrm{TiO}_{2}$ percentage is above $70 \%$ or by using rutile. The production process is referred to as the chloride process.

## Chemistry of the production of titanium dioxide from rutile (Chloride process)

The aim of this process is to remove various inorganic impurities in rutile and produce high purity $\mathrm{TiO}_{2}$. It comprises two steps.

1. Chlorination

## 2. Oxidation

## Chlorination

Drying to remove moisture in rutile and coke is indispensable. For this they are dried well by heating to $200-300^{\circ} \mathrm{C}$.

For chlorination the mixture of rutile and coke is heated to about $950{ }^{\circ} \mathrm{C}$ and stream of chlorine is passed over it. In the presence of coke, titanium dioxide reacts with chlorine giving titanium tetrachloride gas as the product. This reaction is exothermic. The main reason for this is the oxidation of coke giving carbon dioxide. The relevant reactions are,

$$
\begin{aligned}
& \mathrm{TiO}_{2}(\mathrm{~s})+\mathrm{C}(\mathrm{~s}) \longrightarrow \mathrm{Ti}(\mathrm{~s})+\mathrm{CO}_{2}(\mathrm{~g}) \\
& \mathrm{Ti}(\mathrm{~s})+2 \mathrm{Cl}_{2}(\mathrm{~g}) \longrightarrow \mathrm{TiCl}_{4}(\mathrm{~g})
\end{aligned}
$$

The overall reaction is

$$
\mathrm{TiO}_{2}(\mathrm{~s})+\mathrm{C}(\mathrm{~s})+2 \mathrm{Cl}_{2}(\mathrm{~g}) \xrightarrow{950^{\circ} \mathrm{C}} \mathrm{TiCl}_{4}(\mathrm{~g})+\mathrm{CO}_{2}(\mathrm{~g})
$$

The boiling point of $\mathrm{TiCl}_{4}$ is $134{ }^{\circ} \mathrm{C}$. Therefore the exit gas mixture coming out from the reaction chamber mainly contained $\mathrm{TiCl}_{4}$ and $\mathrm{CO}_{2}$. In addition dust particles and as
a result of side reactions hydrogen chloride and carbon monoxide gases may also occur. Here inorganic impurities present in $\mathrm{TiO}_{2}$ are removed. After the removal of dust particles liquid $\mathrm{TiCl}_{4}$ is separated by cooling the gaseous mixture. After further purification of separated liquid $\mathrm{TiCl}_{4}$, it is oxidized.

## Oxidation

Here, $\mathrm{TiCl}_{4}$ produced in the first step is reacted with oxygen and $\mathrm{TiO}_{2}$ is regenerated. This process is important for producing pure $\mathrm{TiO}_{2}$ free of inorganic impurities present in rutile. Resulting chlorine gas is used again for chlorination. Therefore chlorine gas is re-cycled.

$$
\begin{array}{ll}
\mathrm{TiCl}_{4}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \xrightarrow{1000{ }^{\circ} \mathrm{C}} \mathrm{TiO}_{2}(\mathrm{~s})+2 \mathrm{Cl}_{2}(\mathrm{~g}) \\
\mathrm{TiO}_{2}(\mathrm{~s})+\mathrm{C}(\mathrm{~s})+2 \mathrm{Cl}_{2}(\mathrm{~g}) \\
\text { recycling } & \mathrm{CiCl}_{4}(\mathrm{~g})+\mathrm{CO}_{2}(\mathrm{~g}) \\
\mathrm{Cl}_{2}(\mathrm{~g})+\mathrm{TiO}_{2}(\mathrm{~s})
\end{array}
$$

During this process coke is oxidized and carbon dioxide is added to the atmosphere. Hence chloride process contributes to global warming. In 2006, the total amount of $\mathrm{CO}_{2}$ released to the atmosphere by this industry was 3.6 million metric tons. Half of this was due to the burning of fuel to raise the temperature and the other half was produced by the production process.

## Uses of titanium dioxide

1. $\mathrm{TiO}_{2}$ is white in colour. Therefore it is used as a pigment to obtain bright white colour in paint, plastic goods and paper. The high refractive index if $\mathrm{TiO}_{2}$ is also a reason for using it as a pigment.
2. $\mathrm{TiO}_{2}$ is chemically inert. Therefore it is used as a pigment to give white colour to medicine and toothpaste.
3. $\mathrm{TiO}_{2}$ is also used to produce substances applied to prevent sunburns in the skin due to UV radiations in solar rays. $\mathrm{TiO}_{2}$ prevents the reach of UV rays to the skin.
4. It is used to make some solar cells.

### 1.10 Extraction of iron

We have an ancient history of production of iron. Archeological studies have revealed that the ancestors of this country were aware of iron extraction thousands of years ago. They have extracted iron using natural wind power and wood charcoal. Gill Juleff, an archeologist of the university of Exeter, England has confirmed the technology of iron extraction prevailed in this country by recreating an old iron extraction furnace at the wind gap of Balangoda. Her findings have been published in the periodical 'nature' under the title 'An ancient wind-power iron smelting technology'.

## Raw materials essential for iron extraction

- Iron ore
- Limestone
- Coke (coal)
- Air

The furnace used to extract iron using the above raw materials is called the 'blast furnace'. Inside of the blast furnace is lined by a special type of bricks withstanding higher temperatures. The mixture of iron ore, limestone and coke is fed into the blast furnace from the inlet at the top while air is introduced near the bottom. Molten iron is tapped out from the bottom end of the furnace. The slag is removed a little above the level at which molten iron is tapped off. In the blast furnace a mass flow occurs from the top to the bottom under gravity. Simultaneously compressed air passes from the bottom to the top. Since substances flow in opposite directions (from the bottom to the top and from the top to the bottom), possibility for the reactions to occur between the solid phase and the gas phase increases. This also creates a temperature gradient.

Some facts to which attention should be drawn in the process of iron production are given below.

1. Ratio among the components of the mixture of ore, coke and limestone
2. Particle size
3. Rate at which the mixture is added to the blast furnace from the top
4. Rate of flow of the air current and its pressure

Here, the role of coke is as follows.

1. Acts as a fuel

$$
\mathrm{C}(\mathrm{~s})+\mathrm{O}_{2}(\mathrm{~g}) \longrightarrow \mathrm{CO}_{2}(\mathrm{~g})+\text { heat } \quad \Delta \mathrm{H}=-393.5 \mathrm{~kJ} \mathrm{~mol}^{-1}
$$

2. Acts as a direct reducing agent at high temperatures.

$$
\mathrm{FeO}(\mathrm{~s})+\mathrm{C}(\mathrm{~s}) \longrightarrow \mathrm{Fe}(\mathrm{l})+\mathrm{CO}(\mathrm{~g})
$$

3. Generates carbon monoxide which is the main reductant.

$$
\mathrm{CO}_{2}(\mathrm{~g})+\mathrm{C}(\mathrm{~s}) \longrightarrow 2 \mathrm{CO}(\mathrm{~g}) \Delta \mathrm{H}=172.5 \mathrm{~kJ} \mathrm{~mol}^{-1}
$$

Deposition of silicates and aluminates in the ore, should be prevented as impurities in iron. Calcium oxide obtained from the thermal decomposing of calcium carbonate is useful in this regard.

$$
\begin{aligned}
& \mathrm{CaCO}_{3}(\mathrm{~s}) \xrightarrow{89{ }^{\circ} \mathrm{C}} \mathrm{CaO}(\mathrm{~s})+\mathrm{CO}_{2}(\mathrm{~g}) \\
& \mathrm{CaO}(\mathrm{~s})+\mathrm{SiO}_{2}(\mathrm{~s}) \longrightarrow \mathrm{CaSiO}_{3}(\mathrm{l}) \\
& \mathrm{CaO}(\mathrm{~s})+\mathrm{Al}_{2} \mathrm{O}_{3}(\mathrm{~s}) \longrightarrow \mathrm{Ca}\left(\mathrm{AlO}_{2}\right)_{2}(\mathrm{l})
\end{aligned}
$$

Figure 1.11 The blast furnace
Calcium silicate $\left(\mathrm{CaSiO}_{3}\right)$ and calcium aluminate $\left(\mathrm{Ca}\left(\mathrm{AlO}_{2}\right)_{2}\right)$ formed are called the slag. The density of the slag is lower than that of molten iron. Therefore liquid slag layer floats on molten iron. As the slag covers the surface of molten iron, the chances for molten iron to react with oxygen are less.

From the lower part of the blast furnace hot, compressed air is injected into the furnace. Coke burns and with admission of air burning reaction is speeded up. The rate of the burning reaction is decided by the temperature of hot air, pressure and the size of coke particles.

As the combustion reaction is fast and the combustion of coke is highly exothermic large amount of heat is evolved in a short period of time. Therefore the temperature of the basal part of the furnace rises at once to about $1700{ }^{\circ} \mathrm{C}$. The rate of the combustion reaction and the amount of coke burnt are important factors in maintaining the temperature of the basal part stable. It is important to mainain the rate of air flowing upward and the rate of mixture containing coke flowing down to maintain at optimum.

Hot carbon dioxide gas formed during combustion passes upwards through the ore. At high temperatures carbon dioxide reacts reversibly with coke forming carbon monoxide.

$$
\mathrm{CO}_{2}(\mathrm{~g})+\mathrm{C}(\mathrm{~s}) \rightleftharpoons 2 \mathrm{CO}(\mathrm{~g})
$$

Number of gaseous molecules increases. Therefore entrophy increases.
$\Delta \mathrm{S}$ is positive for this reaction (176.5 J). When the temperature increases, magnitude of the numerical value of $\mathrm{T} \Delta \mathrm{S}$ increases. At high temperatures and in the presence of coke (C), there is a tendency for reduction of carbon dioxide to carbon monoxide. Under such conditions CO gas is relatively stable thermodynamically. When the temperature is around $1000{ }^{\circ} \mathrm{C}$ nearly $100 \%$ of $\mathrm{CO}_{2}$ is converted to CO. Figure 1.12 given below shows this variation.

Figure 1.12 Variation of the amount of carbon monoxide against temperature
$\mathrm{O}_{2}(\mathrm{~g})+\mathrm{C}(\mathrm{s}) \longrightarrow \mathrm{CO}_{2}(\mathrm{~g})+$ heat
Number of gaseous molecules does not change
$\qquad$
No considerable change in entropy. Exothermic

$$
\begin{equation*}
\mathrm{O}_{2}(\mathrm{~g})+2 \mathrm{C}(\mathrm{~s}) \longrightarrow 2 \mathrm{CO}(\mathrm{~g})+\text { heat } . \tag{2}
\end{equation*}
$$

Number of gaseous molecules increases

Entropy increases. Exothermic

$$
\Delta \mathrm{G}=\Delta \mathrm{H}-\mathrm{T} \Delta \mathrm{~S}
$$

Because both reactions are exothermic $\Delta \mathrm{H}$ is negative. When the temperature increases reaction (2) has a conspicuous increase in the value of $\mathrm{T} \Delta \mathrm{S}$. With temperature a marked increase in the negative nature of $\Delta \mathrm{G}$ is expected for reaction (2). When the temperature drops thermodynamic stability of CO decreases; thermodynamic stability of $\mathrm{CO}_{2}$ increases.

Since the temperature of the bottom area is as high as $1700^{\circ} \mathrm{C}, \mathrm{CO}$ gas is formed liberating heat when $\mathrm{CO}_{2}$ the gas interacts with red hot coke in the mixture.

When CO gas formed in the hot lower region of the furnace moves up through the mixture containing the ore, the stability of CO decreases because the temperature decreases. Hence the tendency of CO becoming $\mathrm{CO}_{2}$ increases. As oxygen gas is not available in the region above at where coke is burnt in the furnace, CO oxidized to $\mathrm{CO}_{2}$ by reducing $\mathrm{Fe}_{2} \mathrm{O}_{3}$. As a result of this $\mathrm{Fe}_{2} \mathrm{O}_{3}$ is gradually reduced. Going upward the furnace along with the decreasing temperature, so reduction of $\mathrm{Fe}_{2} \mathrm{O}_{3}$ in the ore continues. At temperatures below $1000{ }^{\circ} \mathrm{C}$, reduction of $\mathrm{Fe}_{2} \mathrm{O}_{3}$ can be indicated stepwise as follows.

$$
3 \mathrm{Fe}_{2} \mathrm{O}_{3}(\mathrm{~s})+\mathrm{CO}(\mathrm{~g}) \longrightarrow 2 \mathrm{Fe}_{3} \mathrm{O}_{4}(\mathrm{~s})+\mathrm{CO}_{2}(\mathrm{~g})
$$

$\mathrm{Fe}_{3} \mathrm{O}_{4}$ (ferrosoferric oxide) is a mixture of FeO and $\mathrm{Fe}_{2} \mathrm{O}_{3}$. About $33 \%$ of the iron in +3 oxidation state in $\mathrm{Fe}_{2} \mathrm{O}_{3}$ has reduced to the +2 state.

$$
\begin{aligned}
& 2 \mathrm{Fe}_{3} \mathrm{O}_{4}(\mathrm{~s})+2 \mathrm{CO}(\mathrm{~g}) \longrightarrow 6 \mathrm{FeO}(\mathrm{~s})+2 \mathrm{CO}_{2}(\mathrm{~g}) \\
& \text { or }\left[\mathrm{Fe}_{3} \mathrm{O}_{4}(\mathrm{~s})+\mathrm{CO}(\mathrm{~g}) \longrightarrow 3 \mathrm{FeO}(\mathrm{~s})+\mathrm{CO}_{2}(\mathrm{~g})\right] \\
& \mathrm{FeO}(\mathrm{~s})+\mathrm{CO}(\mathrm{~g}) \longrightarrow \mathrm{Fe}(\mathrm{l})+\mathrm{CO}_{2}(\mathrm{~g})
\end{aligned}
$$

$\mathrm{Fe}_{2} \mathrm{O}_{3}$ partially reduces to $\mathrm{Fe}_{3} \mathrm{O}_{4}$ and this mixture goes down the furnance. There, it further reacts with CO gas and its Fe atoms of +3 state reduce to +2 oxidation state. FeO , which is formed as its result, reacts further with CO gas and reduces up to free iron ( Fe ).

Further, decomposition of $\mathrm{CaCO}_{3}$ occurs at a temperature below $1000{ }^{\circ} \mathrm{C}$ (i.e. $898{ }^{\circ} \mathrm{C}$ ). Carbon dioxide gas generated by it also has the ability to react with coke to produce CO.

Even this produced CO , when going upward the furnace, by reacting with $\mathrm{Fe}_{2} \mathrm{O}_{3}$ in the ore, possible to become $\mathrm{CO}_{2}$.

Above $1000^{\circ} \mathrm{C}$, that is somewhat in the lower part of the blast furnace following reactions occur. In this region coke directly reduces FeO .

$$
\begin{aligned}
& 2 \mathrm{FeO}(\mathrm{~g})+\mathrm{C}(\mathrm{~s}) \longrightarrow 2 \mathrm{Fe}(\mathrm{~s})+\mathrm{CO}_{2}(\mathrm{~g}) \\
& \mathrm{CO}_{2}(\mathrm{~g})+\mathrm{C}(\mathrm{~s}) \longrightarrow 2 \mathrm{CO}(\mathrm{~g}) \\
& 2 \mathrm{CO}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{CO}_{2}(\mathrm{~g}) \quad \Delta \mathrm{H}=-566 \mathrm{~kJ}
\end{aligned}
$$

In the blast furnace a part of the total amount of coke participate for the combustion reaction. Another part reacts with $\mathrm{CO}_{2}$ to produce CO. Another part reduces FeO . Air acting as an oxidant and generates heat and $\mathrm{CO}_{2}$ by the combustion reaction. If excess air is supplied thermodynamically it is likely that in addition to the reaction with $\mathrm{Fe}_{2} \mathrm{O}_{3}$, carbon monoxide would react with oxygen to give carbon dioxide. This is a disadvantage. Therefore in the extraction of iron, it is very important to maintain the volumetric flow rate of air and the flow rate of the solid mixture containing the ore at an optimum level. In the lower part of the furnace the amount of $\mathrm{O}_{2}$ decreases at once but, producing a proportionate amount of $\mathrm{CO}_{2}$. For this reason there is a sudden increase in the concentration of $\mathrm{CO}_{2}$ and production of intense heat. This $\mathrm{CO}_{2}$ in the high temperature zone tends to move up through the solid mixture falling down. Therefore the reaction of $\mathrm{CO}_{2}$ with the coke in the solid mixture occurs in the lower part of the furnace where the temperature is high. Because of this when the $\mathrm{CO}_{2}$ concentration gradually decreases, CO concentration increases. Even CO generated in the lower region passes upwards through the solid mixture. Ascending the furnace the temperature decreases, so the thermodynamic stability of CO gas decreases while the tendency for the conversion to $\mathrm{CO}_{2}$ increases. As $\mathrm{O}_{2}$ is absent CO gas gets oxidized to $\mathrm{CO}_{2}$ gas abstracting oxygen in $\mathrm{Fe}_{2} \mathrm{O}_{3}$. Therefore going upward the furnace, CO concentration decreases and $\mathrm{CO}_{2}$ concentration increases again.

Because of the use of coke $\mathrm{CO}_{2}$ is released from the furnace and this causes global warming. Thus, seeking renewable alternatives for coke is environmentally important. Avoiding unnecessary use of iron is also important.

### 1.11 Polymers

Polymers are formed by the chemical bonding of a very large number of relatively small molecules referred to as monomers.

Examples:

Tetrafluoro ethylene Polytetrafluoro ethylene (PTFE)

Due to the joining of a large number of monomers like this, the carbon skeleton of the monomer is repeatedly placed in the polymer. Therefore it is called the repeating unit.

The repeating unit of polythene (polyethylene or polythene) is $-\mathrm{CH}_{2}-\mathrm{CH}_{2}$-. As there is a large number of repeating units in a polymer molecule. The polymer is symbolized by writing ' $n$ '. Some examples are given in Table 1.2.

Table 1.2 Repeating units of polymers formed by some monomers

| Monomer | Polymer related to the repeating unit |
| :--- | :--- |
| $\mathrm{CH}_{2}=\mathrm{CH}_{2}$ | $-\left(-\mathrm{CH}_{2}-\mathrm{CH}_{2}\right)_{\mathrm{n}}$ |
| $\mathrm{CH}_{2}=\stackrel{\mathrm{Cl}}{1}$ | $-\left(-\mathrm{CH}_{2}-\mathrm{CH}\right)_{\mathrm{C}}$ |
| $\mathrm{CH}_{2}=\mathrm{CH}$ | $-\left(-\mathrm{CH}_{2}-\mathrm{CH}\right)_{\mathrm{n}}$ |

Production of polymers from monomers is called polymerization. According to the reaction occurring in polymerization polymers can be classified into two classes, addition polymers and condensation polymers.

If a polymer is formed by the bonding of monomers by an addition reaction, such a polymer is known as an addition polymer. The unsaturated bonds in the monomer are important in this regard. The molar mass of the monomer is equal to the molar mass of the repeating unit of the polymer. However the three dimensional structure and the hybridization state of the carbon atom of the monomer and the repeating unit change.

During the formation of condensation polymers a condensation reaction occurs. Therefore, in addition to the polymer, small molecules of low mass are produced. For example when an ester bond is formed by the reaction between a -COOH group and $\mathrm{a}-\mathrm{OH}$ group. $\mathrm{H}_{2} \mathrm{O}$ molecule is formed. Hence in the production of polyester a condensation reaction takes place. A number of water molecules equal to the number of ester bonds formed are
released. If the volume of water produced to be measured correctly, the number of ester bonds formed could be calculated using the density and molar mass of water.

$$
\text { Terythalic acid } \quad \text { Ethylene glycol }
$$

In terms of the repeating unit the structure of polyethylene terephthalate (PET) can be shown as above.

Polyamides are obtained by the polymerization reaction between a dicarboxylic acid and diamine. Nylon is such a polyamide. Production of nylon is also a condensation reaction.

The structure of nylon 6, 6 can be indicated as follows using the repeating unit. The first number here represents the number of carbon atoms of the diamine while the second number presents the number of carbon atoms in the dicaboxylic acid.

From the examples used thus to describe the structure of polymers, it is clear that the polymer molecule is created as a single chain. For this reason such polymers are referred to as 'linear polymers'.

Sometimes the polymers are formed as three dimensional networks. The reason for this is that the monomers have more than two reactive sites. If we consider phenol as an example, the number of sites in the benzene nucleus at which substitution can take place is three. A three dimensional network polymer is formed by the reaction between phenol and formaldehyde. The polymer is known as bakelite and the reaction is a condensation reaction.

Figure 1.13 Formation of bakelite by the reaction between phenol and formaldehyde In such instances a specific repeating unit cannot be identified.

According to the nature of the structure polymers can be classified as linear, branched and network. PS, PVC, PTFE and PET polymer molecules have a linear structure.

Linear polymer

Branched polymer

Network polymer

Figure 1.14 Structure of the polymers
Linear and branched polymers are packed in various ways as separate molecules. Sometimes in some regions the molecules are closely packed and orderly arranged. Such regions are called crystalline areas. In some other regions the molecules may be twisted and entwined with one another. Such regions are called amorphous regions. Some polymeric substances are totally amorphous. But some polymers have a certain amount of crystalline regions. Such substances are known as semicrystalline polymers. Polythene is an example for semicrystalline polymers. Light does not penetrate well through the membranes of semi crystalline polymers. Crystalline regions in them scatter light and reduce transparency. Light does not scatter through semicrystalline layers. Therefore they are transparent.

Figure 1.15 How linear and branched polymers are packed

Polyethene can be synthesized so that a branched structure is obtained. Linear polythene molecules pack closely with each other and have more high density areas. Such polyethelene are named High Density Polythene (HDPE). When branched the molecules do not pack that closely. Their density is low and have more amorphous regions. This type of polythene is referred to as Low Density Polythene (LDPE).

### 1.11.1 Rubber and plastic

Rubber is considered as the polymeric material which possess very high elastic properties reversibly. The elastic properties of rubber can be controlled. Starting from monomers, the polymer called rubber can be synthesized. Those are known as artificial rubber (e.g.: nitryl rubber). Highly elastic polymer can be obtained from the latex of the rubber tree too. Those are known as natural rubber (NR).

Polymers with limited elastic properties can be considered as plastics. For example; polymeric substances such as PVC, PET, PP and PE are considered as plastics. When stretched beyond the elastic limit its shape changes irreversibly. Plastic can be classified further as thermoset and thermoplastics. Thermoplastics are composed of linear polymer molecules or branched polymer molecules. Thermoset plastic have a molecular structure arranged as a network. Thermoplastic can be softened by heating. Therefore they can easily be moulded to the required shape by heating. The shape can be made permanent by cooling. PVC, PE, and PS are examples for this. Thermoset polymers cannot be softened like that. Phenol-formaldehyde (bakelite) is an example for this.

### 1.11.2 Natural rubber

Natural rubber (NR) is the substance with high elastic properties obtained by coagulating latex of the rubber tree (Hevea braziliensis). Rubber latex is collected by the systematic removal of the bark of the rubber tree. Rubber latex contains $60-65 \%$ water and $30-35 \%$ rubber. In rubber latex rubber occurs as a colloidal solution in which very small rubber particles are dispersed. Simple sugars and salts are also dissolved in this colloidal solution.

Figure 1.16 A rubber particle

There is a lipid and protein layer around a rubber particle. Inner to it lie rubber molecules. Since $-\mathrm{COO}^{-}$groups associate the outer layers of a rubber partical its outer surface is negatively charged. As electrostatic repulsion forces operate among these negatively charged particles, they are spreaded throughout the solution.

Figure 1.17 Location of negative charges on the outer surface of rubber particles

Because of the repulsive forces among the negatively charged surfaces, the particles do not combine together. In addition of acids $\mathrm{H}^{+}$ions neutralize the $-\mathrm{COO}^{-}$groups and the surface of the particles become electrically neutral. Then the particles combine together and settle down as a mass. This is known as 'coagulation of latex'.

Figure 1.18 Coagulation of latex
Since the rubber latex contains salts, sugar, amino acids etc. It is a suitable medium for microbial action. Because of the acids released by the action of micro-organisms latex coagulates. Therefore, after the collection of rubber latex its coagulation can be prevented by stopping the microbial activity till it is subjected to the production process. The coagulation can be prevented by basifying the latex by adding an ammonia solution. Ammonia prevents the medium becomes acidic and stabilizes the negative charges around the rubber particles. Under these basic conditions the microbial action is suppressed.

In the natural rubber molecule there are two $-\mathrm{CH}_{2}$ groups and one $-\mathrm{CH}_{3}$ groups joined to the doubly bonded carbon atoms in a repeating unit. It is named as cis-1,4 polyisoprene. Gutta percha has a trans structure. This natural polymer is known as trans-1,4-polyisoprene. It does not show elastic properties. There is a maximum distance between the adjacent two $-\mathrm{CH}_{2}$ groups in the trans structure.

cis-1,4-polyisoprene
Polyisoprene can be made synthetically by polymerizing the monomer, isoprene. It belongs to the category of synthetic rubber. They are termed Isoprene Rubber (IR).

Isoprene
In synthetic rubber the monomer is isoprene but we can't say that it is the monomer of natural rubber. In the rubber tree rubber molecules are produced by very complex biochemical reactions.

### 1.11.3 Vulcanizing of natural rubber

Existence of cis-polyisoprene chains is the reason for the elasticity of natural rubber. But to change the elastic property of rubber as required industrially and strengthen it, it is heated with $1-3 \%$ sulphur. This is called vulcanization of rubber. During vulcanization cross links are formed among the poly isoprene chains by sulphur atoms which decrease its elastic property but increase the resilience or the ability to regain its original dimensions. Ebonite is obtained when rubber is heated with $25-35 \%$ sulphur by weight. Ebonite doesn't show elastic properties. This is due to the fact that activity associated with the double bonds in rubber molecules form large number of crosslinks with sulphur atoms. Rubber vulcanized with an optimal amount of sulphur is not sticky and possess an optimum elasticity and high mechanical qualities. Figure 1.19 illustrates how rubber molecules are crosslinked by sulphur atoms.

Figure 1.19 How sulphur crosslinks bind rubber molocules

### 1.11.4 Additives used for the polymer related products

The substances used to improve the qualities of the end product and reduce its production cost in the production of polymers are referred to as additives. Specially by using fillers, the volume required for the end product is obtained. In the production of tyres carbon black is used as the filler. Carbon back improves its physical and mechanical qualities. For example it reduces wear and increases strength. But release of these carbon black particles to the enviornment cause environmental problems. To make vulcanizing efficient various organic catalysts and catalyst promoters such as zinc oxide $(\mathrm{ZnO})$ are used. Most of these organic catalysts are toxic. Various fillers are used for plastics as well. Calcium carbonate is one of them. In the production of plastics, compounds called 'plasticizers' are added to increase their flexibility. For example, PVC pipes used to supply water are hard and rigid but the outer covering of the domestic electric cables made of same material is flexible. This is because PVC of the latter is mixed with plasticizers. Therefore it gets flexibility. In addition to these, additives are added to reduce inflammability and prevent the damage caused by ultraviolet rays. Additives are added in small amounts. Most of the additives added to plastics are phthalates. It has been discovered that many additives distrupt the action of the endocrine systems. Hence much attention should be paid when plastics are used as packaging materials in food storage. Production of plastic goods using PVC is a process where additives are simply used. The reason for this is that in PVC, chlorine atoms are bonded to secondary carbon atoms. Various additives are used to prevent the breaking of $\mathrm{C}-\mathrm{Cl}$ bonds easily. Because of the temperature used in the production process or when those goods are exposed to ultraviolet rays HCl (hydrogen chloride) gets removed from PVC molecules.

### 1.12 Chemical products related to plant sources

### 1.12.1 production of vinegar

Acetic acid is the active ingredients in vinegar. When toddy is subject to continued microbial activity it is oxidized to acetic acid. During this, the amount of acetic acid increases to about $48 \%$. The vinegar so prepared is called natural vinegar. Artificial vinegar is produced by diluting appropriately, the acetic acid obtained by the oxidation of ethanol produced from raw materials turned out by petroleum industry. Natural vinegar contains salts, simple sugars, esters and alcohols in minute quantities.

### 1.12.2 Production of ethanol

Ethanol is used as a solvent for perfumes and scents. It is also used a medium for chemical reactions. The use of ethanol as an environmental-friendly renewable fuel is on increase. Ethanol produced from biomasses by microbial activity is referred to as bioethanol.

Industrially ethanol is produced by hydration of ethylene or fermentation of sugar or starch in the presence of yeast. Alcohol contained in alcoholic beverages is generated by various plant sources.

## E.g. Grapes - vine <br> Barley - Beer

Various cereals, fruit juices, molasses which is a by-product of the sugar industry etc. are used to produce alcohol industrially. As yeast cannot live in a concentrated solution of ethanol, the percentage of ethanol in fermented solution is around $12 \%$.

Products with higher alcohol content are produced by distilling the aqueous solution obtained by fermentation.
E.g. Brandy (about 40\%) - by distilling vine

Arrack (about 40\%) - by distilling coconut toddy
The maximum concentration of ethanol obtainable by the fractional distillation of aqueous ethanol is $96.5 \%$. This is called rectified spirit.

As regards the current use of narcotics and drugs in the world medical specialists state that arrack is one of the most dangerous alcoholic beverage. Let's see what is arrack available in the market. Its main constitutent is ethanol. In the world today there are many methods to produce ethnol. In Sri Lanka too ethanol is produced by some of them. Legally ethanol is produced from fermented coconut toddy and molasses which is a byproduct in the production of sugar form sugar cane.

Coconut toddy is produced by fermentation of sweet toddy, a sugar solution obtained by tapping the tender inflorescence of the coconut tree. The spores of yeast floating in air get deposited in the sweet toddy. During fermentation these grow in the solution using sugar as a substrate. The enzymes produced by the yeast cells gradually convert sugar into ethanol and carbon dioxide.

Within a period of about two days sweet toddy turns into fermented toddy and during this process the sugar concentration gradually decreases.

If fermented toddy is left to stay further, bacteria oxidize alcohol in the toddy converting it to acetic acid. Therefore the alcohol percentage decreases and the acid percentage increases.

Figure 1.20 Variation of the composition of sweet toddy during fermentation

## Fractional distillation

The distillation technique used to separate components which are miscible and have different boiling points from a mixture of them is called fractional distillation.

Table 1.3 Boiling point of some components

| Compound | Melting point $/{ }^{\circ} \mathbf{C}$ |
| :--- | :--- |
| methanol | 64.6 |
| ethanol | 785 |
| propan -1-ol | 971 |
| propan -2-ol | 824 |
| butanal | 747 |
| butanone | 795 |
| ethyl ethanoate | 772 |

Except from coconut toddy ethanol is produced from other plant materials also containing starch Beet, potato, fruits, rice are examples. During the fermentation of these plant sources compounds like esters, aldehydes and ketones are also produced. These too add on to the aqueous mixture. If their boiling points fall within the boiling range of ethanol, they also vaporize with ethanol and pass into the distillate containing ethanol.

In this process the first distillate mainly contains methanol. This is toxic and is used as vine spirit. The second fraction of the distillation mainly contains ethanol. The third fraction obtained at higher temperatures contains higher alcohols and it is called 'fusel oil'.

### 1.12.3 Essential oils

Water - insoluble volatile liquids extracted from plant materials are known as essential oils. Various essential oils have a characteristic smell of their own. They add fragrance to food and increases appetite. Essential oils are also used to make perfumes. In the commercial field of the world today, there is a huge demand for perfumes and flavours. History says that even the kings in the past used fragrances.

Essential oils are obtained from plants such as cinnamon, clove, citronella, cardamom, wintergreen. In plants there are special body parts which contain essential oils.

Table 1.4 Examples for plant parts containing essential oils.

| Part that contain essential oil | Example |
| :--- | :--- |
| Root | Cinnamon, Khus-Khus (Savandara) |
| Stem | Sandle wood |
| Bark | Cinnamon |
| Leaf | Citroriella, lemon grass, eucaliptus, cinnamon |
| Bud | Clove |
| Flower | Jasmine, rose |
| Fruit | Orange, lemon |
| Seed | Cardomom, nutmeg |

## Methods of extracting essential oils

1. Steam distillation
2. Solvent extraction
3. Pressing

## Stem distillation

Many essential oils are likely to decompose or polymerize under the influence of heat. Therefore heating them to high temperatures is not suitable. So, they are subjected to steam distillation and extracted under low temperatures. This phenomenon can be explained by the law of partial pressures. When the systems containing water and plant parts with essential oils are heated, those tissues are damaged and essential oils liberate. The gaseous phase of the system contains water vapour and volatile compounds. At the temperature at which the system boils the sum of the pressures exerted by water vapour and the essential oil vapour is equal to the outer atmospheric pressure. Hence at that temperature if,

Partial pressure of water vapour (saturated vapour pressure) $=P_{\text {H2O }}$
Partial pressure of essential oil (saturated vapour pressure) $=\mathrm{P}_{\mathrm{A}}$
Total pressure of the immiscible system $=\mathrm{P}$
According to Dalton law of partial pressures $\mathrm{P}=\mathrm{P}_{\mathrm{H} 2 \mathrm{O}}+\mathrm{P}_{\mathrm{A}}$

When the total pressure ( P ) becomes equal to the atmospheric pressure, the mixture boils. The boiling point of this mixture is lower than the boiling point of pure water and the boiling point of the essential oil. Therefore essential oil can be distilled at a temperature below $100{ }^{\circ} \mathrm{C}$ and the boiling point of the essential oil.

Figure 1.21 Extraction of essential oil in the laboratory by steam distillation

Steam produced by the steam generator is passed into the vessel which has plant material containing the essential oil. As steam is sent separately or from a steam generator its volumetric flow can be controlled. It is an advantage. When steam enters into the vessel containing plant parts, as plant cells destroy due to the heat of the steam, volatile compounds release. While vapour is condensed, certain amount of water vapour is accumulated in it. Water vapour and essential oil vapour exsist above the liquid water by the continuous flow of water vapour. Then the essential oil in the plant material comes into the vapour phase along with water. However, as water vapour flows continuously, the vapour coming out of the vessel contains essential oil vapour as well as water vapour. When the vapour is passed through a condenser and cooled, the distillate is obtained as two layers of water and essential oil. It can be separated easily.

Example: Main components of cinnamon oil which is obtained by the steam distillation of various parts of the cinnamon tree.

Leaf - eugenol
Bark - cinnamaldehyde
Root - camphor
Main constitution of citronella oil - geraniol

## Solvent extraction

The principle of this is the dissolving of the essential oil in a solvent in which it is more soluble. The solubility of essential oils in water is very low. Nevertheless they are very soluble in organic solvents (e.g. petroleum ether, chloroform, toluene, ethanol). Plant materials are shaken with such a solvent majority of the essential oils pass into the solvent. The solvent is removed by vaporizations or by some other means thereby separating the essential oil.

## Pressing

By applying a suitable pressure on plant materials, the volatile oils in them could be obtained. If pressing is done with another adsorbent, the essential oil is adsorbed into it. For example when a plant material is pressed between two glass slides coated with wax, essential oil in it is adsorbed into wax. Essential oil can then be extracted form wax using another solvent (ether) . Pressing method is rarely used because;

1. The yield is poor
2. Oil gets mixed up with other organic substances

In the extraction of oil from cardamom seeds, pressing method is also used.
Extraction of cinnamon oil is mainly done in areas like Ambalangoda, Hikkaduwa and Baddegama. First Cinnamon leaves are dried in air for 2-3 days in a shady place. Extraction of oil is easier from dried leaves than from fresh leaves. During distillation, essential oil can easily be removed when cuticles of the leaves are broken. It has been found that leaves of the middle age are most suitable than the tender or more mature leaves for oil extraction.

Earlier copper boilers were used for distillation but copper reacts with eugenol in the oil giving a dark colour to the oil. Therefore at present stainless steel or aluminum is used instead of copper.

Generally citronella is grown in Hamabantota district. There are 3 main varieties of citronella.

1. Heen pengiri (Cymbopogon nadus)
2. Maha pengiri (Cumbopogon winterianus)
3. Lenabatu pengiri

Of these the first two types are endemic to Sri Lanka. Cymbopogon winterianus has been introduced by Philippine. The value of citronella oil depends on the occurrence of the compound geraniol. Gereniol is an unsaturated, aliphatic alcohol. Cymbopogon winterianus has a greater demand because it's gereniol content is high.

### 1.12.4 Biodiesel

With the production of engines which can use petroleum fuels efficiently, a rapid development in the field of transport occurred. In modern civilization, the main source of power is petroleum fuel. Easy usage and ability to use safely are their special features. Therefore extraction of petroleum widened rapidly.

Petroleum fuel is a non-renewable source of energy. Therefore in the near future all the petroleum resources in the world will be exhausted. Moreover, in the burning of petroleum fuels carbon occurred as fossils is converted to carbon dioxide. It increases the amount of carbon dioxide in the atmosphere and engenders severe environmental problems such as global warming. For this reason attention is being drawn towards the production of energy using renewable resources. Biodiesel is such a renewable fuel.

Biodiesel is produced from non-volatile plant oils. Plant oil is a renewable resource. Therefore combustion of them does not cause increase in the carbon dioxide content in the atmosphere.

Figure 1.22 Production of biodiesel
Methanol is essential to produce biodiesel. Methanol is obtained from the products of the petroleum industry. Therefore when biodiesel is obtained using methanol is not a biodiesel product produced from $100 \%$ renewable resources. Hence attention is being focused on the production of methanol using carbohydrates and other biomasses employing microorganisms. Methanol so produced is called bio-methanol. Biodiesel produced using biomethanol is biodiesel $100 \%$ based on renewable raw materials.

Biodiesel is produced form the triglycerides present in plant oils. The reaction that converts the fatty acid of these triglycerides into methyl ester (FAME - Fatty acid methyl ester) is refered to as a transesterification reaction. Here, one ester is converted to another ester. A sodium hydroxide solution is used as the catalyst. Biodiesel and glycerol formed
are immiscible and separate out into two layers. The main by-product of this production is glycerol. Hence biodiesel is a mixture of several methyl esters of fatty acids. Biodiesel that has low density floats on the glycerol layer.

If plant oils contain free fatty acid of the type RCOOH they may react with sodium hydroxide to give soap ( RCOONa ). If soap is formed, foam is also formed which inhibits the catalytic action. Thus in plant oils used for this purpose free fatty acid content should be less than $2 \%(\mathrm{w} / \mathrm{w})$ and the acid value should be $0.1 \mathrm{mg}(\mathrm{KOH}) \mathrm{g}^{-1}$.

Production of biodiesel involves several steps.
Step 1 - Treating the plant oil taken as the raw material
Step 2 - Preparation of the catalyst mixture
Step 3 - Reacting triglycerides with methanol
Step 4 -Separating the products
Step 5 - Further purification of crude biodiesel

## Step 1

Free fatty acids and non- saponifiable compounds in the plant oils are removed. This enables to have high yield by the transesterification reaction and maintain a high level of purity of the biodiesel obtained.

## Step 2

Sodium hydroxide catalyst is dissolved in methanol. Afterwards the solution is mixed with triglycerides (plant oil). It is very important that the alcohol does not contain water. The amount of methanol used is also very important. Although the methanol-tryglyceride ratio is $1: 3$, methanol is added in little excess. As the reaction is reversible this makes the reaction more efficient. However methanol is not added in large excess because removal of methanol from biodiesel is difficult. In addition to sodium hydroxide compounds such as potassium hydroxide and sodium methoxide $\left(\mathrm{NaOCH}_{3}\right)$ are used as homogenous catalysts. Compounds like magnesium oxide and zinc oxide can be used as heterogeneous catalysts.

## Step 3

Since the alcohol and plant oil are immiscible, they are mixed with continuous stirring while the temperature is maintained between $50-60^{\circ} \mathrm{C}$.

The trans esterification reaction occurring here produces biodiesel and glycerol.

## Step 4

The main products exist as two phases because they do not mix. The upper layer consists of biodiesel, unreacted triglycerides and diglycerides, and glycerol and methanol in small amounts. Lower layer contains glycerol with excess methanol and the catalyst. After the separation of the phases these layers are separated.

## Step 5

When the biodiesel phase is washed with water glycerol, methanol and the catalysts dissolved in it can be removed. Finally it is possible to remove water.

Remaining methanol may occur in both the layers of biodiesel and glycerol as an impurity. By separating and heating the layers, methanol contained in them can be removed. This methanol can be re-used. Water is bubbled through biodiesel to purify it by removing sodium hydroxide and glycerol which are present in it as impurities. Then, water (moisture) sticking to biodiesel is removed.

In order to prepare a sample of biodiesel, a solution prepared by dissolving 0.75 g of sodium hydroxide in 26 g of methanol and 250 g of soya oil can be used.

Petroleum fuel is a non-renewable source of energy. Petroleum which is a limited natural resource is not uniformity distributed throughout the world geographically. Therefore crude oil has become a very strong and crucial factor in international relations and international politics.As crude oil is used to produce petroleum fuel and the organic compounds obtained from the by-products are used to produce medicine and monomers required to make plastics and artificial rubber, petroleum industry has become the motive force of the modern human civilization. With the combustion of petroleum fuels obtained from the underground crude oil, the carbon dioxide content in the atmosphere rises. Increasing the global warming due to this is a booming threat for the modern human civilization.

## Extra knowledge

Dr. M.K. Hubbert is a geophysicist who described the nature of exhaustion of petroleum, a non renewable resource as against the pattern of human consumption. According to the theory put forward by him (Hubbert peak theory), in a geographical area concerned, the rate of production of petroleum oil varies with time according to a bell-shaped pattern. With the increase in the demand for petroleum with the increasing population and fuel consumption, crude oil production (number of barrels of crude oil production per year) has to be increased. Yet, as the amount of crude oil in the oil wells is limited, there comes a state beyond which the rate of production cannot be increased further. Hence, the amount of barrels of crude oil produced per year comes to a maximum. Meanwhile, the rate of production cannot be maintained at a high constant level because the crude oil resources become more and more limited in
spite of the demand. So, the number of barrels that can be produced yearly gradually decreases causing a decline in the production rate. In 1965, Hubbert, showed that by 1965-70 the amount of barrels of crude oil produced by United States of America reaches a peak. The validity of this prognosis was confirmed when we went past 1970. As per this theory the global production of crude oil reaches the maximum by 2000. Afterwards the yearly production of crude oil would decrease.
Despite the rate of production of crude oil after 1995 was somewhat different from the pattern predicted this theory, today we are basically passing the zone of consumption. Specially, global political factors, alternative sources of power and invention of high efficiency energies etc. have changed this rate of depletion a little. Figure 1.23 (a) depicts the curve suggested by Hubbert with regard to the production of crude oil.

Figure 1.23 Alternative sources of power and fuel efficiency

Presented in Figure 1.23 (b) is a graph based on the Oldvai theory on the spread of annual power production. In this theory, on the production of power in 1930 and prospective production 100 years afterwards (i.e. in 2030) are almost equal. For this reason attention has been focused on the global scale on the production of power using renewable raw materials and synthesizing various organic compounds using them.

### 1.13 Chemistry of air pollution caused by industrial emissions

### 1.13.1 Acid rain

Rain is one component of the water cycle. From the vapourization of water from various sources of water in the Earth's surface water enters the atmosphere. The condensation of this gaseous water due to various factors in the atmosphere and returning back to the surface of the Earth is called precipitation. There are several forms of precipitation. Rain is return as liquid water. Return in solid form occurs as snow and hails. In addition restoration also occurs by condensation into tiny droplets (aerosol) resulting in mist and fogs. Whatever is the way of return, the water coming back to the Earth from the atmosphere is the purest part of the hydrologic cycle. Except the solid particles in the atmosphere and some dissolved gases like nitrogen, oxygen and carbon dioxide there is no other substance in atmospheric water. Of the gases dissolved carbon dioxide has drawn much attention. That is because when atmospheric carbon dioxide dissolves in water, it combines with water to form a weak acid named carbonic acid.

$$
\mathrm{CO}_{2}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow \mathrm{H}_{2} \mathrm{CO}_{3}(\mathrm{aq})
$$

Carbonic acid dissociates weakly and add $\mathrm{H}^{+}$ions to water.

$$
\mathrm{H}_{2} \mathrm{CO}_{3}(\mathrm{aq}) \rightleftharpoons \mathrm{H}^{+}(\mathrm{aq})+\mathrm{HCO}_{3}^{-}(\mathrm{aq})
$$

Therefore pH of rain water is little less than the pH of neutral water.
Based on the present carbon dioxide composition in the air, $400 \mathrm{mg} \mathrm{dm}^{-3}$ or $\mathrm{ppm}(0.04 \%)$, the minimum pH value of rain water is 5.6 . That is, rain water is slightly acidic even in the absence of any other factor affecting it. This mild acidity is not harmful to aquatic organisms, man or any other water related activity. This is the ordinary situation.
But due to various natural and human activities more acidic gases are added to the atmosphere. These are gaseous acidic oxides of nitrogen $\left(\mathrm{NO}_{\mathrm{x}}\right)$ and gaseous acidic oxides of sulphur $\left(\mathrm{SO}_{\mathrm{x}}\right)$. Nitric oxide ( NO ) and nitrogen dioxide $\left(\mathrm{NO}_{2}\right)$ can be considered as the gaseous acidic oxides of nitrogen. Sulphur dioxide $\left(\mathrm{SO}_{2}\right)$ and sulphur trioxide $\left(\mathrm{SO}_{3}\right)$ are the gaseous acidic oxides of sulphur.

Ways of gaseous acidic oxides of nitrogen enter the atmosphere

## Natural process

During lightning where the temperature is high, atmospheric nitrogen reacts with atmospheric oxygen forming nitric oxide $(\mathrm{NO})$ and nitrogen dioxide $\left(\mathrm{NO}_{2}\right)$.

$$
\begin{aligned}
& \mathrm{N}_{2}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{NO}(\mathrm{~g}) \\
& 2 \mathrm{NO}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{NO}_{2}(\mathrm{~g})
\end{aligned}
$$

NO and $\mathrm{NO}_{2}$ are also produced by volcanic eruptions and nitrifying bacteria living in the environment. Gaseous acidic compounds of nitrogen are also produced by the oxidation of ammonia $\left(\mathrm{NH}_{3}\right)$ in the atmosphere which is produced by the microbial decomposition of nitrogenous compounds under anaerobic conditions. The amount of acidic gaseous compounds released to the atmosphere by all these natural process is very small. Thus the composition of naturally produced acidic gases of nitrogen in the atmosphere is very small and has no significant effect on making rain water acidic.

## Human activities

The main anthropogenic (human) activity that emits gaseous acidic compounds of nitrogen to the atmosphere is the burning of fuel in motor vehicles. Internal combustion engines produce energy by combusting liquid fuel in air under a very high pressure and high temperature. Atmospheric nitrogen which is inert under normal condition reacts with oxygen under these conditions of high pressure and temperature mainly producing nitric oxide. Nitric oxide gets oxidized further in the atmosphere giving nitrogen dioxide.

$$
\begin{aligned}
& \mathrm{N}_{2}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{NO}(\mathrm{~g}) \\
& 2 \mathrm{NO}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{NO}_{2}(\mathrm{~g})
\end{aligned}
$$

Acidic $\mathrm{NO}_{\mathrm{x}}$ produced by human activities makes rain water acidic.

## Ways of adding oxides of sulfur to the atmosphere

## Natural ways

In the volcanic eruption, ash and gases containing huge amounts of sulphur dioxide are freed and these directly enter the atmosphere. As a result of microbial activities taking place under anaerobic conditions in the sediments on the bottom of the ocean and water resources hydrogen sulphide gas is produced. Oxidation of this gas in the atmosphere gives sulphur dioxide. However the sulphur dioxide concentration in the atmosphere remains at a very low level because sulphur dioxide produced as above spread across a
very large area of the atmosphere. Sulphur dioxide gas entering the atmosphere due to natural ways hardly contributes to make the rain water acidic. (Acid rains restricted to the relevant areas have been reported after volcanic eruptions.)

## Human activities

Compounds of sulphur includes as impurities in less volatile fuels such as diesel and furnace oil produced during the refining of crude oil. These compounds containing sulphur turn into sulphur dioxide on combustion and enter the atmosphere.

Further, elemental sulphur and sulphur compounds (e.g. FeS) presents as impurities in coal get oxidized during the combustion of coal and enter the atmosphere as sulphur dioxide. Sulphur dioxide produced by human activities like this largely adds on to the atmosphere at certain specific regions. For this reason there could be a very high concentration of sulpher dioxide in the areas around such sites (e.g; coal power stations). Acidic oxide of sulphur $\left(\mathrm{SO}_{x}\right)$ generated by such human activities cause acidity of rain water.

## How $\mathbf{p H}$ is lowered in rain water by acidic gases

NO is produced during the combustion in engines.

$$
\mathrm{N}_{2}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{NO}(\mathrm{~g})
$$

NO in vehicular emissions gets oxidezed in the atmosphere giving $\mathrm{NO}_{2}$.

$$
2 \mathrm{NO}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{NO}_{2}(\mathrm{~g})
$$

In the presence of air $\mathrm{NO}_{2}$ reacts with water and produces nitric acid, a strong acid.

$$
4 \mathrm{NO}_{2}(\mathrm{~g})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})+\mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 4 \mathrm{HNO}_{3}(\mathrm{aq})
$$

$\mathrm{SO}_{2}$ gas entering the air is further oxidized to $\mathrm{SO}_{3}$ gas.

$$
2 \mathrm{SO}_{2}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{SO}_{3}(\mathrm{~g})
$$

$\mathrm{SO}_{3}$ reacts with water vapour to form sulphuric acid. In the presence of air $\mathrm{SO}_{2}$ gas also reacts with water vapour giving sulphuric acid.

$$
\begin{aligned}
& \mathrm{SO}_{3}(\mathrm{~g})+\mathrm{H}_{2} \mathrm{O}(1) \longrightarrow \mathrm{H}_{2} \mathrm{SO}_{4}(\mathrm{aq}) \\
& 2 \mathrm{SO}_{2}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \longrightarrow 2 \mathrm{H}_{2} \mathrm{SO}_{4}(\mathrm{aq})
\end{aligned}
$$

The compounds $\mathrm{HNO}_{3}$ and $\mathrm{H}_{2} \mathrm{SO}_{4}$ formed above are strong acids. They completely ionize in water adding $\mathrm{H}_{3} \mathrm{O}^{+}$ions to water in large amounts.

Because of the $\mathrm{H}_{3} \mathrm{O}^{+}$ions added to water by the strong acids, the pH value of water decreases below the pH caused by carbonic acid formed by dissolving $\mathrm{CO}_{2}$ gas.
Lowering of pH in rain water below 5.6 by adding strong acids to the rain is called acidification of air or formation of acid rain. High acidity of water leads to many problems.

## Effects of the acidification of water

Aquatic organisms are very sensitive to the change of pH in water. Therefore even a small drop in pH in water is harmful to them. This causes changes in behavioural patterns, retardation of organogeny and destruction of eggs and immature organisms of fish and other aquatic organisms etc. This is detrimental to biodiversity.

Figure 1.24 Distroying of aquatic organisms

Figure 1.25Destroying of forests

Death of coral polyps responsible for the formation of coral reefs stops their formation and bleaches the reefs.

Continuous fall of acid rains in forested areas leads to degradation of chlorophyll in plant leaves which causes gradual death of the plants. Death of plants from their top to bottom is a sign of their ruin brought about by acid rains.

Acid rains make soil acidic. Owing to the acidity, poisonous metal ions $\left(\mathrm{Al}^{3+}, \mathrm{Cd}^{2+}, \mathrm{Cr}^{2+}\right.$, $\mathrm{Hg}^{2+}$ ) and other toxic ions strongly bound to the insoluble soil structure get detached and dissolve in water. Increased concentration of these ions is harmful to aquatic organisms and not suitable for human consumption.

## Examples :

High concentration of $\mathrm{Al}^{3+}, \mathrm{Fe}^{3+}$ and heavy metal ions such as is very harmful to aquatic organisms.
High acidity rain water brings about speedy dissolving of micronutrient metal ions in the soil such as $\mathrm{Fe}^{3+}, \mathrm{Zn}^{2+}$ and $\mathrm{Cu}^{2+}$ in water which are then leached out easily. This makes soil infertile.

Acid water dissolves rocks and minerals in soil containing calcium, magnesium and aluminum. Excessive ions of these in water raises the hardness of water.

Acidity increases the rate of corrosion of metal structures in constructions. This weakens their mechanical strength and reduces the life time.

Acid rains damage statues and other artistic creations made of calcium carbonate minerals such as marble. This obliterates their fine carvings denigrating their historic value.

It decreases the mechanical strength of houses and other constructions made by mortar and cement which contain lime stone. Acid rains and acidic gases convert the less soluble corbonates in mortar and cement into more soluble sulphates and nitrates.

$$
2 \mathrm{CaCO}_{3}+2 \mathrm{SO}_{2}+\mathrm{O}_{2}+2 \mathrm{H}_{2} \mathrm{O} \longrightarrow 2 \mathrm{CaSO}_{4} \cdot 2 \mathrm{H}_{2} \mathrm{O}+2 \mathrm{CO}_{2}
$$

## Measures that could be taken to reduce acid rains and acidification of water

1. Using coal and diesel with low sulphur content in coal and diesel power plants.
2. Adopting methods to remove acidic gases like sulphur dioxide like acidic gases emitted by power plants.
(i) Burning coal with substances $\left(\mathrm{CaCO}_{3}\right)$ that can react with sulphur dioxide (Fluidized bed combustion)

$$
\begin{aligned}
& \mathrm{CaCO}_{3}(\mathrm{~s}) \longrightarrow \mathrm{CaO}(\mathrm{~s})+\mathrm{CO}_{2}(\mathrm{~g}) \\
& \mathrm{CaO}(\mathrm{~s})+\mathrm{SO}_{2}(\mathrm{~g}) \longrightarrow \mathrm{CaSO}_{3}(\mathrm{~s})
\end{aligned}
$$

(ii) Converting sulphur dioxide in power plant waste gases into solid substances. (reacting with calcium hydroxide (Lime slurry process))

$$
\mathrm{Ca}(\mathrm{OH})_{2}(\mathrm{aq})+\mathrm{SO}_{2}(\mathrm{~g}) \longrightarrow \mathrm{CaSO}_{3}(\mathrm{~s})+\mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

3. Employing environmental-friendly fuels or alternative energy sources such as solar energy, wind power, tidal energy, geothermal energy and nuclear power in place of coal and diesel.

### 1.13.2 Global warming

For all natural process and dynamic activities carried out by man on the Earth, energy is provided by the sun. There is an empty space between the sun and all the other plants including the Earth. Because of this reason solar energy travels to the Earth as radiations. This radiant energy comes to the Earth mainly as visible, infrared and ultraviolet radiations. Radiation energy of the Sun reaching the Earth like this are subjected to various transformation in the Earth. Finally leaves the Earth. That is to say, there is an energy equilibrium in the Earth.
Because of the transformations undergone by the radiant energy reaching the Earth, heat is generated in the Earth. As a result the earth gets heated up and reaches a certain temperature. Because of the transformation of solar energy, its return and establishment
of an equilibrium, the extent to which the earth is heated remains constant. Therefore on the whole the average temperature of the Earth is assumed to be a constant value. This is about $15^{\circ} \mathrm{C}$. However due to Earth's $23.5^{\circ}$ inclination to its axis's situation of latitude intensity of solar energy received by various regions is different. Because of this seasonal changes the temperature in different parts of the world in various time intervals is different.

For example, in equatorial regions the temperature is high and it is uniform throughout the year. From the equator to polar regions seasonality becomes acute and temperature within the year varies with in wide limits. The summer is extremely hot while the winter is intensely cold. In polar regions an extremely cold weather prevails throughout the year.

The average temperature of the Earth, that is $15{ }^{\circ} \mathrm{C}$ is a favorable condition for the existance of life. The reason for the prevalence of the favourabe temperature is the green house effect existing on the Earth. The potency of the green house effect on the earth helps to maintain an optimum temperature favourable for life.

## Greenhouse effect

Before studying the greenhouse effect let us understand what a greenhouse is. As we all know, to grow an agricultural crop a certain optimum temperature is essential throughout the life of the crop. When we go from the equator of the Earth to mid latitude regions, the annual period of time with this optimum temperature gradually decreases. On reaching the polar regions, the time with optimal temperature necessary for plant growth becomes so short that plants do not grow in those regions. If plants grow at all, they are plants with a very short life span (e.g. The life span of plants growing in Tundra regions is about 2-3 weeks). In mountain regions a low temperature prevails year-long (e.g. Nuwara Eliya, Bandarawela etc.).

Hence, life in a particular region, if the time interval during which the optimum temperature necessary for a certain crop is less than its life span, growing that crop in the relevant, region is difficult. A greenhouse lengthens this period of optimal temperature without an external heat supply in a safe house located in that particular region. The temperature in a greenhouse is higher by $2{ }^{\circ} \mathrm{C}$ to $6^{\circ} \mathrm{C}$ than the temperature outside. For this reason, even outer temperature is lower than the optimal temperature, it can be maintained that optimum temperature inside the greenhouse. In a greenhouse the time period with optimal temperature can be extended by 2-3 weeks longer than that in the normal environment. Now let's inquire into how this happens.

## Action of a greenhouse

A greenhouse is an almost completely safe kept house. Its roof and walls are made of transparent material so that solar rays can penetrate them. Through these transparent materials visible and ultraviolet radiations coming from the sun, passes into the greenhouse.

Inside the greenhouse, these radiations are absorbed by the soil and other substances in it. A part of the radiant energy absorb is re-emitted as low energy ultraviolet and visible radiations while another part is re-radiated as infrared radiations. The roofing materials and materials for the walls of the greenhouse are selected in such a way that they are transparent for the visible and UV radiations but reflect IR radiations. When IR rays are reflected inside the greenhouse for a longer

Figure 1.26 A Greenhouse period of time they are absorbed by carbon dioxide and water vapour and are converted to heat. This increases the temperature inside the greenhouse. This is the process takes place inside a green house. The atmosphere of the Earth too exhibits a process somewhat equal to the action of greenhouse. This is known as the greenhouse effect of the earth.

## Greenhouse effect of the earth

Solar radiations falling on the Earth are mainly belong to the ultraviolet and visible zones. Of these most of the radiations belonging to the ultraviolet zone are absorbed by the upper atmosphere and very little reaches the Earth's surface. It is UV radiations of very low energy that come like this. Visible ray and low energy UV rays reaching the Earth surface are absorbed by the Earth's surface (soil) and re-radiated as low energy radiations like in a greenhouse. In this re-radiation energy is emitted as low energy visible rays and IR rays. The emitted visible rays return to space without undergoing any significant change. But the IR radiations emitted could be absorbed by certain gases in the air. Fortunately the main gases in the air $-\mathrm{N}_{2}(78 \%), \mathrm{O}_{2}(21 \%), \mathrm{Ar}(1 \%)$, cannot absorb these IR radiations. If these gases occupying more than $99 \%$ of the Earth's atmosphere had absorbed IR radiations, the temperature of the earth could have been very high.

## Greenhouse gases

The gases which can absorb infrared radiations exist stably in the atmosphere for a long period of time are referred to as greenhouse gases.

Any gas having two or more atoms can absorb IR radiations. Also a hetero diatomic gases (e.g CO) can absorb IR radiations. Homo diatomic gases $\left(\mathrm{N}_{2}, \mathrm{O}_{2}\right)$ and monatomic gases (e.g. Ar) cannot absorb IR rays. Hence any gas which is not monatomic and homo diatomic can absorb IR rays. Nevertheless, if a gas is to act as a greenhouse gas in the Earth's atmosphere, it should have following characteristics.

## 1. Ability to absorb infrared rays

2. Ability to stay stably in the atmosphere for a long period of time.

The gases in the atmosphere which are though capable of absorbing IR rays, unstable
or short-lived are not considered greenhouse gases. As per the foregoing facts the main greenhouse gases present in the atmosphere are,

1. Water vapour $\left(\mathrm{H}_{2} \mathrm{O}\right)$
2. Carbon dioxide $\left(\mathrm{CO}_{2}\right)$
3. Methane $\left(\mathrm{CH}_{4}\right)$
4. Nitrous oxide $\left(\mathrm{N}_{2} \mathrm{O}\right)$
5. Volatile halogenated hydrocarbons (CFC, HFC, HCFC)

Although would be present in certain amounts in the atmosphere and they are capable of absorbing IR rays, the gases such as $\mathrm{SO}_{2}, \mathrm{NO}_{2}, \mathrm{NO}$ and CO are not reckoned as greenhouse gases. This is because their life span in the atmosphere is very short. Of the above greenhouse gases, all the gases except halogenated hydrocarbons exist in nature.

The greenhouse gases aforementioned absorb IR rays emitted from the Earth and retain them long in the Earth. Therefore the Earth gets heated. The result of this heating is the maintenance of the normal temperature of the earth at around $15^{\circ} \mathrm{C}$. Thus greenhouse effect is favourable factor essential for the perpetuation of life.

## Extra knowledge

The hottest planet in our solar system is not Mercury which is closest to the Sun but the second from it, Venus. Venus receives about $25 \%$ of the solar energy received by Mercury. The reason for this is the strong greenhouse effect existing in Venus. Around $95 \%$ of the atmosphere of Venus comprises carbon dioxide gas. For this reason, the atmosphere of Venus largely absorbs infrared rays and creates a strong greenhouse effect. Hence, though situated second from the sun, Venus holds the record of being the hottest planet of the solar system.

The percentages of greenhouse gases in the Earth are given in Table 1.5.
Table 1.5 Amounts of greenhouse gases in the Earth

| Greenhouse gas | Quantity |
| :--- | :--- |
| Water vapor (\%) | $0.001-0.5$ |
| Carbon dioxide (ppm) | 415 |
| Methane (ppb) | 1745 |
| Nitrous oxide (ppb) | 315 |
| Volatile halogenated hydrocarbons | 53.3 |
| (CFC, HFC, HCFC) (ppt) |  |

What would happen if the percentage of greenhouse gases in the Earth increases? The
outcome is production of more heat in the Earth due to absorption of more IR radiations by the increased amount of greenhouse gases. The heat so produced circulated longer in the Earth causing an increase in Earth's temperature. Along with the industrial ventures initiated by man with the industrial development the proportion of greenhouse gases is gradually increasing. It increased rapidly with the industrial awakening got under way after the second world war started with the industrial revolution.

Table 1.6 Changes in the composition of greenhouse gases before the industrial revolution and at present.

| Gas | Composition in 1750 <br> (Volume percentage) | Present composition <br> (Volume percentage) |
| :--- | :--- | :--- |
| $\mathrm{CO}_{2}$ | 0.028 | 0.041 |
| $\mathrm{CH}_{4}$ | 0.00007 | 0.00018 |
| $\mathrm{~N}_{2} \mathrm{O}$ | 0.000027 | 0.0000314 |
| Halogenated hydrocarbons | 0 | 0.00000000533 |

From Table 1.6 it is clear that the amount of all greenhouse gases has drastically increased.
Though the amount of water vapour in the earth atmosphere changes with geographical factors and some weather factors on short-term, the total amount of water vapour in the Earth remains unchanged on long-term. Because of this, although water vapour is a greenhouse gas it does not contribute to global warming. Owing to the increase in greenhouse gases the temperature of the Earth has risen by about $0.95{ }^{\circ} \mathrm{C}$ from 1750. This increase is $0.65^{\circ} \mathrm{C}$ from

Figure 1.27 Impact of the increase in the temperature of the Earth 1950. This shows that global warming has rapidly increased during the few decades in the recent past.

## Human activities leading to the increase in greenhouse gas concentration Carbon dioxide ( $\mathrm{CO}_{2}$ )

To meet the energy requirement of man, coal and petroleum are being burnt in excessive amounts. The carbon reserves which occurred inertly inside the Earth for millions of years were burnt in a very short time adding the resulting $\mathrm{CO}_{2}$ to the atmosphere. When the rate of addition of $\mathrm{CO}_{2}$ to the atmosphere exceed the rate of the mechanisms which remove $\mathrm{CO}_{2}$ from it, $\mathrm{CO}_{2}$ gas accumulates in the atmosphere.

Because of excessive deforestation, trees are felled indiscriminately. The debris contain carbon reserves collected over hundred of years. When these are decomposed by the microbial activity $\mathrm{CO}_{2}$ is added to the atmosphere. This causes the carbon dioxide content in the atmosphere to rise.

## Methane

When the indiscriminately disposed organic wastes decay in the environment they are acted upon by anaerobic bacteria. When those bacteria decompose organic substances methane is produced. Disposal of urban wastes as heaps of garbage is also a reason for the production of methane in large amounts. Agricultural practices (paddy cultivation) undertaken in marshy and water-logged areas favour anaerobic decomposition of organic substances producing methane.
Methane is also produced in the guts of the ruminants like cattle, sheep and goats due to bacterial decomposition of plant material under anaerobic conditions. Therefore rearing such animals in commercial scale is a reason to release methane in large amounts to atmosphere. Crude oil mining too increases the methane content in the atmosphere. During the mining process methane gas occurring as natural gas in crude oil deposits is freed to the atmosphere.

## Nitrous oxide

Oxides of nitrogen are mainly added to the atmosphere by the bacterial action on nitrogenous compounds. Action of denitrifying bacteria on the nitrogen compounds added to the soil as fertilizers in agriculture produces nitrous oxide $\left(\mathrm{N}_{2} \mathrm{O}\right)$.

## Gaseous halogenated hydrocarbons

Halogenated hydrocarbons are very powerful greenhouse gases. These are ten thousand times as strong as carbon dioxide. For this reason, presence of these gases in the atmosphere even in small quantities contributes significantly to global warming.
Halogenated hydrocarbons are scare in nature. Halogenated hydrocarbons responsible for increasing the global warming are,

1. Chlorofluorocarbon (CFC)
2. Hydrochlorofluorocarbon (HCFC)
3. Hydrofluorocarbon (HFC)

HCFC 22

HCFC 123

HFC 32

HFC 134a

Figure 1.28 Some halogenated hydrocarbon molecules

All these three types are compounds synthesized by man and are used as cooling gases in air conditioners and refrigerators. They are also used as a blowing agent in the production of perforated plastics and in aerosols, for example in deodorant sprays and pesticides. In repair and disposal of the above equipment these compounds enter the atmosphere. The atmospheric lifetime of these are hundreds of years.

## Adverse effects of global warming

- With the global warming polar ice caps and glaciers in high mountains areas tend to melt while the oceanic waters expand. This entails in inundation of costal lowlands. (e.g. Ganges river in Bangladesh, the delta of river Brahmaputra, Mekong delta in Vietnam). Loss of settlements, destruction of costal ecosystems, infertility of soil caused by the sea water swamping inland and devastation of crops are the other outcomes of this. Moreover it may obliterate Maldives and many other small island states in the pacific ocean completely from the world map.
- Because of the high temperature epidemics (e.g; dengue, Ebola)

Figure 1.29 Melting of ice caps in polar regions spread fast.

- Increase in the number of hot days and decrease in the number of cold days per year, occurrence of strong heat waves more frequently and lasting for a longer period of time (rapid increase in the temperature in regions within a small time interval).
- Frequent emergence of hurricanes, tornadoes etc. of greater violence.
- Rapid spread if invasive plants and animals. Such plants and animals may encroach new areas (cold blooded animals like snakes and other reptiles would migrate to cooler areas).
- Excessive drying of some regions (South Asia, Central Africa) while some other regions (e.g. Europe) receive heavy rainfall.
- Frequent long-standing droughts and flash floods due to heavy rainfall in a short period of time.

## Global climatic changes

Many human activities in the world are connected with the climate of the relevant region. For examples, agriculture, animal husbandry, tourism and pottery are strongly linked to climatic patterns. These climatic patterns are created by the differences in solar energy received by various parts of the world. The shift of energy circulation caused by global warming brings about changes in the climatic patterns.
Not receiving rain on time, untimely rains, droughts and occurrence of whirl winds and tornadoes in regions where they have not been experienced before are examples. Prolonged droughts causing desertification in some regions forcing people to leave those areas. Climatic changes may indirectly engender political crises among nations and even battles.

For example, when the citizens of a certain country are displaced they migrate to neighbouring countries and a need arises to provide political asylum for them. Political crisis and wars may erupts for sharing water in rivers common to several countries (e.g. Nile, Brahmaputra, Mekong) specially when water goes scarce.
Global warming and climatic changes caused by it, is a problem common to the entire world. The most affected by this are the underdeveloped and developing countries which contribute least to global warming. So, in order to control global warming all the countries in the world should get together and have to adopt measures that minimize the emission gases which cause it.

The following solutions could be suggested in this regard.

- Limited the burning of fossil fuels and inclining to use alternative fuels. The best option is sloar energy. In addition nuclear power and wind power be used. Updating the machinery of current use and increasing their fuel efficiency could also be done.
- Instead of fossil fuels it is suitable to use renewable sources of energy such as ethanol and biodiesel. The amount of pure carbon added to the atmosphere by the combustion of bio-fuels is nil.
- By getting used to a simple lifestyle, high energy demand essential for a luxurious life can be minimized.
- Minimizing deforestation. To make furniture and paper and obtain firewood, fastgrowing plants can be used without destroying forests.
- Avoiding indiscriminate waste disposal and adopting systematic method of waste disposal with proper management of waste. This minimize the emission of methane to the atmosphere.
- Refraining from the consumption of meat as much as possible getting used to vegetarian diet. By this rearing of animals such as cattle, goats and sheep for meat can be minimized.
- Use of compost in place of chemical fertilizers. This helps minimize the emission of nitrous oxide $\left(\mathrm{N}_{2} \mathrm{O}\right)$ to the atmosphere.
- Restricting the use of refrigerators and air conditioners and using in such machines with less powerful gases such as hydrofluroolefines (HFO), isobutene (R600a) and coolant gas like ammonia in place of more stronger greenhouse gases like CFC and HCFC.

### 1.13.3 Depletion of the ozone layer

Energy for all the process taking place in our planet Earth is provided by the sun. Energy is transmitted from one place to another by three methods, conduction, convention and radiation. Of these, conduction and convention need a medium for the transmission of energy. Radiation does not require a medium for energy transmission. In our planetary system an empty space (vacuum) occurs between the sun and the planets. Therefore there is no possibility at all to transmit energy from the Sun to the Earth by conduction and convention. Hence the solar energy reaches the Earth by radiation which does not need a medium. The radiation that carry energy from the Sun to the Earth are known as electromagnetic radiations.
Electromagnetic radiations are classified according to the energy in them. That is as X-rays, ultraviolet rays, visible rays, infrared rays, micro waves and radio waves. Table 1.7 indicates the properties of various electromagnetic waves.

Table 1.7 Properties of electromagnetic waves

| Electromagnetic <br> waves | Mean wave length | Mean frequency/ $\mathbf{s}^{\mathbf{- 1}}$ | Mean energy/ <br> $\mathbf{k J ~ m o l}$ <br> $\mathbf{- 1}$ |
| :--- | :--- | :--- | :--- |
| Radio waves | 1 cm | $3 \times 10^{10}$ | $1.2 \times 10^{-2}$ |
| Micro waves | 1 mm | $3 \times 10^{11}$ | $1.2 \times 10^{-1}$ |
| Infared waves | $10 \mu \mathrm{~m}$ | $3 \times 10^{13}$ | 12 |
| Visible waves | 500 nm | $6 \times 10^{14}$ | 240 |
| Ultraviolet waves | 250 nm | $1.2 \times 10^{15}$ | 479 |
| X ray | 1 nm | $6 \times 10^{17}$ | $1.2 \times 10^{5}$ |

Of these X-rays and ultraviolet rays are highly energetic. Therefore when exposed to them they cause chemical changes in the bio-molecules in our body. The structural changes in the active bio-molecules in our body namely DNA, RNA and proteins (enzymes) obstruct their functions causing various complication in our bodies. We discuss these complications at length under the sections to come.

Energy is transmitted from the Sun to our planet Earth mainly in the form of ultraviolet rays, visible rays and infrared rays. Of these visual rays and infrared rays are low in energy and we are not harmed by the exposure to them. In the electromagnetic spectrum the only ray type sensitive to our eyes are visible rays and they help to give us the sense
of vision. We become sensitive to infrared by sensing heat.
Figure 1.30 illustrates the nature of the solar rays reaching the Earth and their intensity. From it we see that a considerable portion of the solar energy reaching the upper limit of the Earth's atmosphere are lost before reaching the earth's surface. Further examination of the figure, reveals that most of the UV rays have been eliminate before they reach the Earth's surface. Why does it happen so? It is because the absorption of those rays by the gas molecules in the upper strata of the atmosphere while the solar rays travel to the Earth's surface across the atmosphere.

Figure 1.30 Stratification of Earth's atmosphere and penetration of strata by solar radiations

## Stratification of the atmosphere

For the convenience of studying the atmosphere is divided into several layers. This stratification is based on the variation of temperature and the density of the gases in respective regions.
Troposphere This stretches from the Earths surface to about 15 km upwards. A greater percent (about 99\%) of the atmospheric gases is found in this region.

Ascending from the Earth's surface, the temperature decreases.
Stratosphere The region from 15 km to 50 km from the Earth's surface is stratosphere. The percentage of gases here is very low and ascending the layer, the temperature increases.

Thermosphere
It is the region above 50 km from the Earth's surface. Amount of gases in this region is extremely small and the temperature is very high.

Ozone layer A sub-zone in the stratosphere is referred to as the ozone layer. This extends from 20 km to about 35 km from the Earth's surface. This is called ozone layer because most of the naturally occurring ozone gas in the Earth (around 95\%) is found in this region. However it should be remembered that this is not composed only of ozone.

Figure 1.31 Ozone layer and the stratification of Earth's atmosphere
A greater part of the UV rays received from the Sun is spent to maintain the ozone gas in the ozone layer in the stratosphere. Therefore most of the harmful UV radiations coming from the Sun does not reach the Earth's surface. In other words, the ozone layer protects us from being exposed to higher energy UV rays by acting as a filter to them. This phenomenon is vital for the survival of life on the Earth. It is important for the maintenance of the life as much as the existence of water and an optimum temperature.

## Functioning of the ozone layer

When higher energy UV rays coming from the Sun reach the stratosphere, they decompose oxygen gas and produce atomic oxygen.

$$
\begin{equation*}
\mathrm{O}_{2}(\mathrm{~g}) \xrightarrow{\boldsymbol{h} \boldsymbol{v}} \mathrm{O}(\mathrm{~g})+\mathrm{O}(\mathrm{~g}) \quad \Delta \mathrm{H}>0 \tag{1}
\end{equation*}
$$

As this atomic oxygen is very reactive it reacts with another oxygen molecule forming ozone.

$$
\begin{equation*}
\mathrm{O}_{2}(\mathrm{~g})+\mathrm{O}(\mathrm{~g}) \longrightarrow \mathrm{O}_{3}(\mathrm{~g}) \quad \Delta \mathrm{H}<0 \tag{2}
\end{equation*}
$$

Ozone is an unstable gas. In the presence of UV rays it decomposes giving oxygen.

$$
\begin{align*}
& \mathrm{O}_{3}(\mathrm{~g}) \xrightarrow{\boldsymbol{h} \boldsymbol{\nu}} \mathrm{O}_{2}(\mathrm{~g})+\mathrm{O}(\mathrm{~g}) \quad \Delta \mathrm{H}>0  \tag{3}\\
& \mathrm{O}_{3}(\mathrm{~g})+\mathrm{O}(\mathrm{~g}) \longrightarrow 2 \mathrm{O}_{2}(\mathrm{~g}) \quad \Delta \mathrm{H}<0  \tag{4}\\
& \text { (1) }+(2) \times 2,3 \mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{O}_{3}(\mathrm{~g}) ; \mathrm{O}_{3} \text { formation } \\
& \text { (3) }+(4), 2 \mathrm{O}_{3}(\mathrm{~g}) \longrightarrow 3 \mathrm{O}_{2}(\mathrm{~g}) \text {; breaking of } \mathrm{O}_{3}
\end{align*}
$$

In the ozone layer when the rates of breaking and making of ozone like this become a dynamic equilibrium sets in maintaining a fixed amount of ozone in this region. i.e. the following equilibrium exists in the ozone layer.

$$
2 \mathrm{O}_{3}(\mathrm{~g}) \rightleftharpoons 3 \mathrm{O}_{2}(\mathrm{~g})
$$

As UV rays coming from the Sun are absorbed in maintaining this equilibrium, the entry of those harmful rays to the Earth's surface is prevented.

## Depletion of the ozone layer

The ozone level in the ozone layer was continuously measured from 1950 with the aid of weather balloons. During making this measurement an amount of the ozone level in the ozone layer was observed decreasing annually from mid-seventies.
Generally the ozone level in the ozone layer does not remain constant every day. It changes to some extent with the temperature of the environment, seasonal changes and geographical factors. But annually it drops gradually. This continuous decrease in the ozone level in the ozone layer is, called ozone layer depletion. Depletion of ozone layer is a serious environmental problem.
The ozone layer prevents the entry of harmful UV rays to the Earths' surface. Because of the depletion of ozone layer in upper levels more harmful UV rays reach the Earth's surface. Exposure of the Earth's inhabitants more to the harmful UV rays causes various complications in them.

## Causes for ozone layer depletion

Both natural factors and human activities cause ozone layer depletion. Of these the natural causes are temporary and the damage made is recovered in a short period of time. Sulphur containg compounds added to the upper atmosphere during powerful volcanic eruptions
is one natural factor damaging the ozone layer.
The most severe and non-reversible damages to the ozone layer are brought by the human. This is caused by the volatile compounds released to the atmosphere by man.

Examples are,

1. Chlorofluorocarbon

In addition to this, volatile organic compounds containing bromine (bromofluorocarbon) indirectly contribute to ozone layer depletion.
2. Nitric oxide (NO) gas emitted by the aircrafts flying close to the upper atmosphere also depletes the ozone layer.

The main class of compounds which contributes to ozone layer depletion is chlorofluorocarbons. These are derivatives of hydrocarbons with one or two carbon atoms. Of these, all the hydrogen atoms are replaced by chlorine or fluorine.

Freon 12

Freon 11

Freon 113

Freon 115

Figure 1.32 Some CFC molecules and their industrial names

All CFCs are synthetic compounds and not found in nature. Mainly they have the following industrial applications.

1. Used as the coolant gas in air conditioners and refrigerators
2. Used as an aerosol spray under high pressure in perfumes
3. Used as a blowing agent in the production of foam plastic (e.g.: polystyrene, cushions, mattresses, thermal insulating porous walls) to give porosity to them
4. Bromofluorocarbons are used in fumigation and in fire extinguishers.

## How CFCs and other compounds damage the ozone layer

We should remember that none of the above compounds react directly with ozone. The CFCs describe above are very stable compounds. They are not thermally decomposed and are resistant to bio-degradation. For this reason these compounds can stay long in the atmosphere. However, these compounds are very volatile. Hence, they can evaporate rapidly and reach the stratosphere which accommodates the ozone layer where they are exposed to high energy UV rays in upper atmosphere which do not found in lower atmosphere. Under the influence of these $\mathrm{C}-\mathrm{Cl}$ bonds undergo fission producing Cl free
radicals. These free radicals react with ozone. They catalyze the breakdown reaction of ozone speeding it up and adding another process of breakdown other than to the natrual breakdown of ozone. Because of this the ozone-breaking process outstrips the ozone making process and the ozone layer is subjected to degradation. This can be illustrated by the following equations.

Cl free radicals react with ozone

$$
\begin{equation*}
{ }^{\circ} \mathrm{Cl}(\mathrm{~g})+\mathrm{O}_{3}(\mathrm{~g}) \longrightarrow \mathrm{O}_{2}(\mathrm{~g})+{ }^{\prime} \mathrm{OCl}(\mathrm{~g}) \tag{1}
\end{equation*}
$$

OC1 free radicals formed react with oxygen atoms formed by the natural breakdown of ozone and regenerates free radical.

$$
\begin{align*}
& \mathrm{O}_{3}(\mathrm{~g}) \longrightarrow \mathrm{O}_{2}(\mathrm{~g})+\cdot \mathrm{O}(\mathrm{~g})  \tag{2}\\
& \mathrm{OCl}(\mathrm{~g})+\cdot \mathrm{O}(\mathrm{~g}) \longrightarrow \mathrm{O}_{2}(\mathrm{~g})+\cdot \mathrm{Cl}(\mathrm{~g})  \tag{3}\\
& (1)+(2)+(3), \\
& 2 \mathrm{O}_{3}(\mathrm{~g}) \longrightarrow 3 \mathrm{O}_{2}(\mathrm{~g})
\end{align*}
$$

This shows that after the decomposition of an $\mathrm{O}_{3}$ molecule by a C 1 free radical the C 1 free radical is regenerated without being destroyed. That means, until getting destroyed by another reaction a ${ }^{\circ} \mathrm{C} 1$ free radical can decompose a large number of $\mathrm{O}_{3}$ molecules. Hence C 1 free radicals have acted as a catalyst in the breakdown of $\mathrm{O}_{3}$ molecules.

## Adverse effects of ozone layer depletion

The main adverse effect of ozone layer depletion is the entrance of high energy, harmful UV rays in high intensity to the Earth's surface. A grater amount of such UV rays gains admission to the Earth's surface after the degradation of the ozone layer than that reached to the Earth's surface before its degradation. Then Earth's creatures expose more to the harmful, high enegy UV rays and become victims to their injurious effects.

Listed below are such unfavourable effects.

1. Skin cancer

Due to high energy in UV rays, exposure to them brings about structural changes in the molecules like DNA in the skin cells. In the presence of UV radiations, hydrogen bonds in these large molecules break and rearrange in another way. These molecular deforemations give birth to cancer cells which spread fast in the skin ultimately causing cancer.
2. Cataract in eyes

DNA molecules as well as proteins maintain their structure through hydrogen bonds.
Under the influence of the UV rays these bonds break and rearrange changing the
structure of proteins. The eye lens which is essential for vision is made up of a transparent, semi-solid protein. Owing to UV rays, the structure of the proteins in the eye lens changes and its transparency gradually decreases. This is called cataract (e.g.:when transparent egg white is heated it becomes white. This is because the structure of the protein albumin in egg white changes on heating). Cataract in the eye happens not only in humans but also in animals like cattle and goats which live mostly outdoor.
3. Mutations

Plants with gene mutations would arise when they are excessively exposed to UV rays (e.g.: dwarf plants, plants with deformities in leaves)
4. Bleaching

UV rays bleach pigments in cloths and degrade their quality.

## Measures to be taken to protect the ozone layer

If the ozone layer goes on degrading at the rate it is happening at present, the Earth will become a place unsuitable for the perpetuation of life; or it would be a place where eye cataract and skin cancer patients are omnipresent.

Therefore immediate action should be taken to reduce the rate of ozone layer depletion. As CFC is the main destroyer of the ozone canopy its production and usage should be stopped. Action has already been taken in this regard and the Montreal Convention ended the production of CFCs from about 1996. At present alternative gases are being used for the industrial applications for which CFCs were used.

HCFC (Hydrochlorofluorocarbon) was the first alternative gas used for CFCs. This molecule is very much similar to CFC and the only difference was presence of a hydrogen atom in addition to chlorine and fluorine atoms.

HCFC 22
(a)

HCFC 123
(b)

HFC 32
(c)

HFC 134 a
(d)

Figure 1.33 (a) and (b) some HCFC molecules and (c) and (d) some HFC molecules

The C-H bond is this molecules is disassociated by solar rays carrying relatively lower energy than the energy in the lower atmosphere. For this reason a considerable part of this compound is decomposed before it reaches the ozone layer. But due to high volatility this gas also can reach the stratosphere. If it reaches the ozone layer like this it has the potential to damage the of ozone layer by cleavage of the $\mathrm{C}-\mathrm{Cl}$ bond under the influence of high energy UV rays and formation of Cl free radicals. The other alternative used to protect the ozone layer is the use of hydrofluorocarbon (HFC) gas as the coolant in refrigerators. HFCs lack chloride atoms and have only fluorine and hydrogen atoms. Their stability is also low due to the existence of hydrogen atoms (as in HCFC) but they do not form Cl free radicals in the upper atmosphere for they do not contain chlorine atoms. Therefore they do not damage the ozone layer. Hence the coolant use in the airconditions and refrigerators in the world today is HFC (HFC 134a).

Note : Though HFC gas does not harm the ozone layer HFC, CFC and HCFC all are very powerful greenhouse gases. The global warming potential (GWP) of these gases is thousand times the GWP of carbon dioxide.

Table 1.8 Greenhouse gases and their GWP values

| Gas | GWP value |
| :--- | :--- |
| $\mathrm{CO}_{2}$ | 1 |
| $\mathrm{CH}_{4}$ | 22 |
| $\mathrm{~N}_{2} \mathrm{O}$ | 310 |
| HFC 23 | 11700 |
| HFC 134a | 1300 |
| CFC 12 | 10600 |
| HCFC 22 | 1700 |

Despite the fact that the above gases occur in the atmosphere in very small concentrations (ppt), they can contribute considerably to increase global warming because of their very high GWP values. HFC is a good alternative for the ozone layer depletion. But its use is questionable because it contribute to another global environmental issue, the global warming. This has prompted the global community to use cooling gases that do not damage the ozone layer and contribute little to global warming.
Use of volatile hydrocarbons (e.g. R600a) and unsaturated hydrofluorocarbon compounds (Hydrofluoroolefin) (e.g. HFO-1234a) which are less stable in the atmosphere has been already started as alternatives. Isobutene (industrially labeled R600a) is being used as a volatile hydrocarbon. Usage of hydrofluoroolefin (HFO) have been prescribed as an
unsaturated hydrofluorocarbon. HFO is structurally similar to HFC and has a double bond. As compounds with double bonds are more reactive, HFO compounds decompose faster in the lower atmosphere and get removed. Thus their contribution to global warming is very low.

Figure 1.34 (a) Isobutene (R600a) (b) hydrofluoroolefin (HFO - 1234a)

### 1.13.4 Photochemical smog

Are you a person living in a town congested traffic jams? If so, have a look over the town form a fairly tall building in an afternoon. You will able to see a less transparent, brown coloured mist above the relevant buildings. On less windy days with a clear sky this could be seen in areas close to towns like Pettah, Borella, Kaduwelan and Kandy. Though somewhat rare in Sri Lanka this is a dreadful common in towns like New Dilhi, Mumbai, Culcata, Shanhai, Bejing and Kuala Lumpur.

What is the reason that gives rise to this kind of a less transparent, browny haze in afternoons? The complex photochemical process leading to this phenomenon is called photochemical smog. Photochemical smog means the lowering of the transparency of the atmosphere due to scattering of solar rays by chemical substances formed by the interaction of several environmental pollutants, fine particles and droplets of water.

## Chemical pollutants causing photochemical smog and their sources

Two types of chemical pollutants contribute to the photochemical smog. They are nitric oxide gas (NO) and volatile hydrocarbons (unburnt fuel). In addition to these sunlight and a temperature above $15^{\circ} \mathrm{C}$ are requirements.

Chemical pollutants causing photochemical smog are $\mathbf{N O}, \mathbf{C H}_{3}\left(\mathbf{C H}_{2}\right)_{\mathrm{n}} \mathbf{C H}_{\mathbf{3}}(\mathrm{n}=\mathbf{1 - 4})$
Both these chemical substances are added to the air almost totally by the transportation by automobiles. Hydrocarbons are the main component of liquid petroleum fuels. The transportation of vehicles totally depends on liquid petroleum. These fuels filled into vehicles enter the environment as unburnt fuel in various ways. Because of the high volatility of gasoline fuel, they vaporize from the fuel tank of vehicles and the volatile hydrocarbons release to the enviornment. A considerable amount of hydrocarbons vaporizes from the carburetor as well. Yet, the largest amount of them enters the air
through the exhaust system of the vehicle. Although fuel is burnt in the engine of the vehicle under high temperature and pressure, all the fuel molecules entering the piston do not burn. Especially the hydrocarbon molecules lying closer to the outer wall of the piston do not burn. These unburnt fuel molecules are released to the atmosphere via the exhaust system.

Inside the engine, fuel is burnt by mixing fuel and air in an optimum ratio and igniting under high pressure. Due to the heat evolved by the combustion a high temperature and pressure are created in the engine. Under this high temperature and pressure nitrogen which is considered as an inert gas under normal conditions, reacts with oxygen to produce nitric oxide. This nitric oxide gas escapes into the air through the exhaust system of the vehicle. Accordingly both the pollutants causing the photochemical smog are added to the air by the transportaion of vehicles. This is the reason why the photochemical smog is intense in urban areas with lot of traffic jams.

## Chemistry of the photochemical smog

The photochemical smog is a result of a series of complex chemical reactions happening in the lower atmosphere under the influence of sunlight. But to make the study facile, the reactions occurring in the photochemical smog can be simplified as follows.

Nitric oxide gas released from internal combustion engines is subjected to further oxidation in the atmosphere producing nitrogen dioxide. $\mathrm{This}_{\mathrm{NO}_{2}}$ when exposed to solar rays, get decomposed forming atomic oxygen.

$$
\begin{aligned}
& 2 \mathrm{NO}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{NO}_{2}(\mathrm{~g}) \\
& \mathrm{NO}_{2}(\mathrm{~g}) \xrightarrow{\boldsymbol{\nu} \boldsymbol{v}} \mathrm{NO}(\mathrm{~g})+\mathrm{O}(\mathrm{~g})
\end{aligned}
$$

Atomic oxygen reacts again with molecular oxygen $\left(\mathrm{O}_{2}\right)$ forming ozone $\left(\mathrm{O}_{3}\right)$ which is a main pollutant in the photochemical smog.

$$
\mathrm{O}(\mathrm{~g})+\mathrm{O}_{2}(\mathrm{~g}) \longrightarrow \mathrm{O}_{3}(\mathrm{~g})
$$

Formation of ' OH free radicals: $\mathrm{O}(\mathrm{g})+\mathrm{H}_{2} \mathrm{O}(\mathrm{g}) \longrightarrow \mathrm{OH}(\mathrm{g})$
In addition to these, OH free radicals and ozone which is formed by atomic oxygen react with volatile hydrocarbon forming alkyl and proxyalkyl free radicals. These alkyl ( $\mathrm{R}^{\prime}$ ) and proxialkyl ( $\mathrm{ROO}^{\circ}$ ) free radicals react with $\mathrm{NO}_{2}$ and $\mathrm{O}_{2}$ producing harmful volatile short chain aldehydes, preoxyactyle nitrate (PAN) and peroxybenzyl nitrate (PBN). Aldehydes produced are subjected to polymerization forming small particles suspended in air. Large particles are formed by these small particles by the deposition of dust, water vapour etc. on them. These particles scatter sunlight reducing the transparency and it appear like a mist in the lower atmospere. Photochemical smog is the only state of pollution visible to our naked eye.

## Adverse effects of the photochemical smog

- Ozone is produced as a main product of the photochemical smog. Ozone is a toxic gas. When inhaled it causes respiratory complaints destruction of mucous membranes in the respiratory tract, cough etc.
- Ozone is an unstable and very reactive gas. Therefore when plants are exposed to ozone yellow spots appear especially in tender leaves due to destruction of chlorophyll. This cuts down food production resulting in retardation of growth and decrease in the yield of agricultural crops.
- Ozone spilts the double bonds in rubber molecules (ozonolysis). This shortens the chains of rubber molecules reducing the mechanical strength of rubber-based products. It also causes reduction in the elasticity of rubber and splits in rubber tyres.
- Many volatile aldehydes are produced by the photochemical smog. Inhalation of these compounds causes respiratory diseases and the people who are suffering from asthma, wheezing, bronchitis etc., their ailing conditions get worst and exacerbate. Inhalation of these compounds, also can cause allergic conditions.
- Peroxyacetyl compounds (PAN and PBN) produced by photochemical smogs are carcinogenic and cause gene mutations. They bring about chemical changes in active proteins and enzymes in the body and disrupt the action of enzymes.
- Ozone bleaches colourings. Therefore they deteriorate the quality of textiles.

### 1.14 Chemistry of the water pollution caused by industrial emissions

Water is one factor indispensable for the survival of life on the Earth. That is for the reason that water contributes to biochemical reactions and acts as the solvent for those reactions. Further, water also acts as the solvent for the natural environmental reactions. Water acts as the solvent for the bio-environmental reactions like this because of the exceptional properties of the water molecule. As regards the geometrical shape of water molecule is angular (Figure 1.35).

Figure 1.35 Geometrical shape of the water molecule
The value of its HOH angle is $104.5^{\circ}$. Due to the difference in the electronegativities of the elements H and O of $\mathrm{O}-\mathrm{H}$ bond in the water molecule, is polar. Since the two polar $\mathrm{O}-\mathrm{H}$ bonds are angularly situated in space, the water molecule has a resultant polarity. This polarity is around 1.85 D (Debye). This has made the water molecule a strongly polar molecule. Because of this high polarity, strong hydrogen bonds form among the
water molecules. Therefore bulk water occurs as a liquid at room temperature. That is, water is a strongly polar liquid and because of this high polarity many polar compounds dissolve in water. Water is a good solvent for polar compounds. Many natural compounds as well as the compounds taking part in biochemical processes too are polar. For this reason water acts as a solvent for biochemical and environmental process. Hence water is named environmental polar solvent in environmental chemistry.

In the property of being a good solvent for polar compounds, there are demerits in water also. Many unwanted polar compounds readily dissolve in water and pollute it. Dissolving of various substances in water making it unsuitable for the relevant task, is called water pollution. Water pollution differs according to the task for which it is meant. For example there are occasions where water considered polluted for the drinking purpose, is reckoned unpolluted as far as agriculture is concerned. Water polluted by micro-organisms making it unsuitable for food processing is suitable to obtain steam.

Although the water is a strong polar solvent non-polar compounds also dissolve slightly in it. Some such non-polar compounds are highly toxic and even if dissolved in traces it would be at a harmful level. For example the solubility of benzene which is a very strong carcinogen, in water is about 1780 parts per million ( 1780 ppm ). But for the drinking water parameters the maximum permissible value for benzene is 5 parts per billion ( 5 $\mathrm{ppb})$. That is to say solubility of benzene in water is 350,000 times higher the permissible level. From this we can conclude that water is polluted by dissolving of polar as well as non-polar compounds in it. Oxygen is a completely non-polar molecule, yet oxygen is slightly soluble in water ( 8 ppm ). This oxygen which is slightly soluble in water, is a vital factor for all the aquatic organism for their living processes. All the biological processes in the aquatic organisms occur because of this slightly dissolved oxygen in water.

### 1.14.1 Water cycle and water pollution

Figure 1.36 shows an environmental water (hydrological) cycle. This indicates the exchange of water among various sectors of the environment. Water is liable to get contaminated in every stage in this cycle. The least polluted water in the cycle is atmospheric water (clouds, water vapour, fog, frost and rain water). Water enters the atmosphere by evaporation of ground water. Since the boiling point of most of the polar compounds (salts etc.) dissolved in water is high, those compounds do not enter the atmosphere with the evaporation of water. For this reason water entering the atmosphere by evaporation is the purest and least polluted water in the environment. However, volatile polar compounds $\left(\mathrm{H}_{2} \mathrm{~S}, \mathrm{NH}_{3}, \mathrm{NO}_{2}\right)$ dissolve in water in the atmosphere. Besides, various chemical compounds produced by photochemical process $\left(\mathrm{NO}_{2}, \mathrm{SO}_{2}, \mathrm{H}_{2} \mathrm{SO}_{4}, \mathrm{HNO}_{3}, \mathrm{NH}_{4} \mathrm{NO}_{3}\right.$ etc.) in the atmosphere also dissolve in atmospheric water. Further, very small suspended particles (dust, pollen, bacteria etc.) found in the atmosphere blend with atmospheric water and pollute it.

Figure 1.36 Water cycle
This atmospheric water reaches the Earth's surface by way of precipitation in the form of rain, snow, frost, fog and hales. Because of the runoff across the Earth's surface a portion of water reach the Earth's surface, is polluted further. It is also contaminated by the dissolving of salts formed by the weathering of minerals (heavy metal salts), various salts in the soil and various chemicals produced and added to the environment by man (fertilizers, industrial chemicals, agrochemicals). A part of water reaching the Earth's surface by rain percolates to the interior of the Earth (ground water) through the layers of rocks. When water passes through the layers of rocks and minerals, these layers decay. As a result, various mineral salts dissolve in water polluting the ground water as well.

### 1.14.2 Water quality parameters

As we have mentioned before, many polar as well as non-polar substances dissolve more or less in water. Since, though dissolve in large amounts, are not harmful (e.g. NaCl ) Some are very toxic even when dissolved in minute quantities (e.g. heavy metal ions). For this reason it is essential to measure the suitability of water for the task in which it is used. For this, maximum and minimum thresholds or ranges with regard to the dissolved and undissolved substances have been stipulated. These pre-determined standards are called water quality parameters. Various countries and international institutions have published parameters for drinking water and parameters for releasing waste water. When the indicators fall outside the limits of these parameters, water is considered not suitable for the particular task.

Table 1.9 indicates the maximum level or the range of constituents published by the Sri Lanka Standards Institute for water suitable for domestic use.

Table 1.9 Domestic water quality parameters published by the Sri Lanka
Standards Institute, Sri Lanka

| Parameter | Unit | Maximum value or range |
| :--- | :--- | :--- |
| Colour | Hazen Units | 15 |
| Turbidity | NTU (Nephelometric |  |
|  | Turbidity Unit) | 2 |
| pH | - | $6.5-8.5$ |
| Chemical oxygen demand (COD) | $\mathrm{mg} \mathrm{L}^{-1}$ | 10 |
| Total dissolved solids | $\mathrm{mg} \mathrm{L}^{-1}$ | 500 |
| Hardness (as $\mathrm{CaCO}_{3}$ ) | $\mathrm{mg} \mathrm{L}^{-1}$ | 250 |
| Total phosphate $\left(\mathrm{as} \mathrm{PO}_{4}^{3-}\right)$ | $\mathrm{mg} \mathrm{L}^{-1}$ | 2.0 |
| Arsenic $\left(\right.$ as As $\left.{ }^{3+}\right)$ | $\mathrm{mg} \mathrm{L}^{-1}$ | 0.01 |
| Cadmium $\left(\mathrm{as} \mathrm{Cd}^{2+}\right)$ | $\mathrm{mg} \mathrm{L}^{-1}$ | 0.003 |
| Lead (as $\left.\mathrm{Pb}^{2+}\right)$ | $\mathrm{mg} \mathrm{L}^{-1}$ | 0.01 |
| Mercury $\left({\left.\mathrm{as} \mathrm{Hg}^{0} \text { and } \mathrm{Hg}^{2+}\right)}^{\mathrm{mg} \mathrm{L}}\right.$ |  | 0.001 |

### 1.14.3 Waste Water quality parameters

Let us consider some waste water quality parameters very briefly.

## pH value

Here, pH stands for the 'potential of hydrogen'. The pH scale means a scale that expresses the magnitude of acidity or alkalinity of a solution. pH value is the negative logarithm of the hydrogen ion concentration given in $\mathrm{mol} \mathrm{dm}^{-3}$.

There are several methods to determine the pH value of a solution.

1. By a titration or some other method: $\mathrm{H}^{+}$ion concentration of the solution is determined. By taking its negative logarithm, pH value can be found very accurately.
2. Using pH indicators ( pH papers change colour according to the $\mathrm{H}^{+}$ion concentration in the solution): An approximate value for pH can be obtained by soaking a pH paper in the relevant solution and comparing the colour with a standard pH colour scale.
3. Using a pH meter: The potential of a special electrode (glass electrode) which changes with the $\mathrm{H}^{+}$ion concentration of the solution is measured relative to a standard electrode $(\mathrm{Ag} / \mathrm{AgCl}$ electrode) and the pH value is read directly.

Figure 1.37 presents pH values of some common aqueous solution which we come across in our day to day life. It has been decided that the pH range of drinking water in Sri Lanka should be $6.5-8.5$.

Figure $\mathbf{1 . 3 7} \mathrm{pH}$ value of some aqueous solutions met in day to day life

## Conductivity

The conductivity of an aqueous solution is a measure of the ability of the respective solution to conduct electricity. For this there must be free ions in water. The conductivity of pure water is very low. Pure water contains a very small amount of $\mathrm{H}^{+}$and $\mathrm{OH}^{-}$ions formed by the self-ionization of water $\left(1.0 \times 10^{-7} \mathrm{~mol} \mathrm{dm}^{-3}\right)$. The major cause for the conductivity of water is the amount of salts dissolved in water. When salts get dissolved in water they separate into cations and anions which occur as hydrated ions. As these ions are movable in water, they move towards the electrodes when a potential difference is applied, giving rise to conductivity. Water-soluble inorganic salts and organic compounds which can dissociate into ions (organic acids and bases) contribute to conductivity. The organic compounds like glucose and sucrose which dissolve in water but do not dissociate into ions, have very small contribution to the conductivity of water. The conductivity meter is used to measure the conductivity. The unit of measuring conductivity is siemens per centimeter $\left(\mathrm{S} \mathrm{cm}^{-1}\right)$. But in many aqueous solutions which we often come across the conductivity expressed in $\mathrm{S} \mathrm{cm}^{-1}$ takes a very small value, so microsiemens per centimeter ( $\mu \mathrm{S} \mathrm{cm}^{-1}$ ) is used as the unit.

The conductivities of some aqueous solutions which we find in our day to day life are given in Table 1.10.
G. C. E. (A/L) CHEMISTRY - UNIT 14 Industrial Chemistry and Enviornmental Pollution

Table 1.10 Conductivities of some aqueous solutions which we find in our day to day

| Solution | Conductivity $/ \mu \mathrm{S} \mathrm{cm}^{-1}$ |
| :--- | :--- |
| Deionized water | $0.1-5$ |
| Distilled water | $1-10$ |
| Drinking water | $50-1000$ |
| Milk | 1000 |
| 0.01 M KCl solution (standard solution <br> for conductivity measurements) | 1410 |
| Ground water | $100-8000$ |
| Sea water | $2000-60000$ |
| Apple juice | 10000 |
| Concentrated acids | $60000-900000$ |

## Turbidity

Clean water is fully transparent; i,e, light passes through it without any obstruction. But due to addition of various foreign substances, water loses its transparency and appears cloudy. The loss of transparency in water like this is referred to as turbidity. The turbidity is caused by the presence of undissolved, suspended particles, that is fine particles which do not settle under the gravity in water. Because of these small particles light passing through water is scattered. Then, the sample of water appears cloudy or foggy. Presence of suspended particles is one visible instance in water pollution.

Existence of fine colloidal particles in water also leads to its turbidity. Fine clay particles, very small organic and inorganic particles, colonies of small unicellular organism and fine polymer particles are the suspended particles causing turbidity in water.

In order to gauge the turbidity in water, how much of a beam of light is scattered or transmitted by water is measured. The measurement is done by comparing the amount of light scattered by the solution concerned with the amount of light scattered by a solution of known turbidity. The unit of measuring turbidity is Nephlometric Turbidity Unit (NTU). Figure 1.38 shows the NTU values of some solutions with standard turbidity.

Figure 1.38 NTU values of a solution series with standard turbidity

## Hardness of water

Are you living in the dry zone of Sri Lanka? Or have you ever drunk water drawn from a well or taken from any other source when you have visited such an area? Recall the taste of water you consumed. You would remember that the water is brackish in taste. Perhaps you would have observed that your hair becomes sticky and rough after bathing in that water. Why does it happen so? The brackish taste and roughness in hair were due to the high level of hardness in water.

The hardness of water is defined the capacity of water to precipitate soap. The chemical species causing the hardness in water are the polyvalent metal cations dissolved in water. It is the total concentration of $\mathrm{Ca}^{2+}, \mathrm{Mg}^{2+}, \mathrm{Fe}^{2+}, \mathrm{Mn}^{2+}, \mathrm{Al}^{3+}$ and any other polyvalent metal cations. In natural water, the most abundant polyvalent metal cations are $\mathrm{Ca}^{2+}$ and $\mathrm{Mg}^{2+}$ ions. Therefore $\mathrm{Mg}^{2+}$ and $\mathrm{Ca}^{2+}$ are the two cations almost contribute to the hardness of natural water. But very rarely there are instances where ions like $\mathrm{Mn}^{2+}, \mathrm{Fe}^{2+}$ and $\mathrm{Al}^{3+}$ also contribute to hardness. Soap is sodium or potassium salts of fatty acids. The carboxylate groups of these salts combine with polyvalent metal cations to form polyvalent metal cation slats of fatty acids. As these salts are less soluble in water they get precipitated. Since the density of this precipitate is less than that of water it floats on water as a soap scum. Hence soap does not function as a cleaning agent until all these polyvalent metal cations are removed. Also, these polyvalent metal cations neutralize the naturally occurring negative charges on the surface of hairs. Then, the hair which repelled one another due to the surface charges on them before come together making them sticky due to the loss of charges.

The permanent hardness in water has no relationship with the anions (e.g. $\mathrm{Cl}^{-}, \mathrm{SO}_{4}^{2-}$ ) present in water. The unit of expressing the hardness in water is parts per million calcium carbonate ( $\mathrm{ppm} \mathrm{CaCO}_{3}$ ). The hardness level of water are classified approximately as follows (Table 1.11).

Table 1.11 The hardness level of water

| Calcium carbonate/ $\mathbf{m g ~ L}^{-1}$ | The quality of water |
| :--- | :--- |
| $0-50$ | Soft |
| $50-100$ | Moderately soft |
| $100-200$ | Slightly hard |
| $200-300$ | Moderately hard |
| $300-450$ | Hard |
| $450+$ | Very hard |

## Temporary hardness

The presence of hydrogen carbonate (bicarbonate) ions and carbonate ions at a concentration above the total concentration of the polyvalent metal cations is temporary hardness. This is called temporary hardness because it can be removed by boiling of water. On boiling, the relevant metal cations are precipitated as their carbonates.

$$
\begin{aligned}
& \mathrm{Ca}^{2+}+2 \mathrm{HCO}_{3}^{-} \xrightarrow{\Delta} \mathrm{CaCO}_{3}+\mathrm{CO}_{2}+\mathrm{H}_{2} \mathrm{O} \\
& \mathrm{Mg}^{2+}+2 \mathrm{HCO}_{3}^{-} \xrightarrow{\Delta} \mathrm{MgCO}_{3}+\mathrm{CO}_{2}+\mathrm{H}_{2} \mathrm{O}
\end{aligned}
$$

## Permanent hardness

The presence of carbonate ions and hydrogen carbonate (bicarbonate) ions at a concentration very much below the total concentration of polyvalent metal cations is known as the permanent hardness.
This is termed permanent hardness because here, the metal ions existing in a concentration above the equivalent concentration of carbonate and bicarbonate ions cannot be precipitated by boiling. Permanent hardness can be removed by adding water-soluble carbonates (e.g. $\mathrm{Na}_{2} \mathrm{CO}_{3}$ ) from outside.

$$
\mathrm{Ca}^{2+}+2 \mathrm{Cl}^{-}+\mathrm{Na}_{2} \mathrm{CO}_{3} \longrightarrow \mathrm{CaCO}_{3}+2 \mathrm{Na}^{+}+2 \mathrm{Cl}^{-}
$$

## Chemical oxygen demand (COD)

The chemical oxygen demand in water is the amount of oxygen required to oxidize the oxidizable substances dissolved in water. The most abundant oxydizable substances present in water are the various organic compounds. These occur in different oxidation states and can finally be oxidized to carbon dioxide or carbonates. Fatty acids, ammonia acids, sugars like glucose and fructose, starch and proteins are among these compounds. Inorganic species like $\mathrm{Fe}^{2+}$ and $\mathrm{Mn}^{2+}$ ions also contribute to the chemical oxygen demand of water. COD of water is determined by a titration. The sample is distilled with a known amount of acidified potassium dichromate solution, a strong oxidant. The remaining
amount of dichromate ions is titrated with a standard $\mathrm{Fe}^{2+}$ solution and the value of COD value is determined.

Mostly the COD value is measured in the waste water discharged by industries. That is because when waster water with high COD is added to water bodies they get polluted.

Maximum COD values of waste water prescribed by the Central Environmental Authority of Sri Lanka for release into different water bodies are given in Table 1.12.

Table 1.12 Maximum COD values recommended by the Central Environmental Authority of Sri Lanka for release into different water bodies

| Effluent | Maximum COD value/ $\mathbf{m g ~ L}^{\mathbf{- 1}}$ |
| :--- | :--- |
| Industrial effluents to surface water | 250 |
| Industrial effluents to irrigation | 400 |
| Industrial effluents to marine water | 250 |
| Effluents from rubber factories | 400 |
| Effluents from textile factories | 250 |

## Disisolved oxygen level

The dissolved oxygen level (DO) is defined as the amount of molecular oxygen $\left(\mathrm{O}_{2}\right)$ dissolved in a unit volume of water. The dissolved oxygen comprised the oxygen gas directly dissolved from the $21 \%$ of oxygen present on the atmosphere and dissolving of oxygen gas produced by the photosynthetic aquatic plants and organisams (e.g.: algae, cyanobacteria) in the presence of sunlight. Because water molecule is polar and oxygen molecule is non-polar, solubility of oxygen in water is very low. For example at $21^{\circ} \mathrm{C}$ temperature and 1 atm atmospheric pressure at sea level the dissolved oxygen level in water is nearly $9 \mathrm{mg} \mathrm{L}^{-1}$ ( 9 ppm ). Owing to various chemical and biological process occurring in water, the dissolved oxygen level in water decreases. When the dissolved oxygen level in water goes below 5 ppm , aquatic organisms are subjected to stress. In a situation like this, stress symptoms such as fish swimming to the water surface and keeping their mouths open to the atmosphere can be observed. When this value drops to $1-2 \mathrm{ppm}$ fish start to die. Sometimes we have heard about sudden deaths of thousands of fish in reservoirs of different parts of the country. The main reason for such an incident is the slump of DO to a very low value.

When the DO decreases to a very low level (close to 0 ppm ) anaerobic conditions set in water. This occurs in the bottom of deep lakes and tanks. There are several methods to determine the DO level in water.

1. Direct measurement using an oxygen meter/ probe sensitive to dissolved oxygen
2. By a titration (Winkler method) In this the DO level is determined by a back titration.

In this method, first dissolved oxygen is reacted with manganese ion $\mathrm{Mn}^{2+}$ in the basic media to form manganese dioxide.

The manganese oxide formed is reacted with iodide ions in an acid medium.

The liberated iodine is then titrated with a standard thiosulphate solution.

$$
\begin{aligned}
& \mathrm{I}_{2}+2 \mathrm{~S}_{2} \mathrm{O}_{3}^{2-} \longrightarrow 2 \mathrm{I}^{-}+\mathrm{S}_{4} \mathrm{O}_{6}^{2-} \\
& 1 \mathrm{~mol} 2 \mathrm{~mol}
\end{aligned}
$$

Four moles of thiosulphate are used up for one mole of oxygen. In the laboratory you can determine the DO level of various water samples by this method.
according to (1), (2), (3)

$$
\begin{aligned}
& \mathrm{O}_{2}=\mathrm{MnO}_{2}=\mathrm{I}_{2}=\mathrm{S}_{2} \mathrm{O}_{3}^{2-} \\
& 1 \mathrm{~mol} \quad 2 \mathrm{~mol} \quad 2 \mathrm{~mol} \quad 4 \mathrm{~mol}
\end{aligned}
$$

## Eutrophication

The excessive growth of algae due to addition of nutrients to the water is defined as eutrophication.

When algae grow in abundance they form a thick blanket of their colonies on the water surface. This cuts down the penetration of sunlight to the lower layers of water bodies and prevents photosynthesis happening in them. This reduces the level of dissolved oxygen close to the bottom resulting in the death of aquatic plants and animals. When the dead bodies of these plants and animals are decomposed by aerobic bacteria, the DO level goes down further creating anaerobic conditions. Under anaerobic conditions gases like hydrogen sulphide are produced which make the area foul-smelling. Various nutrients are essential for algae growth but in many instances the limiting nutrient seems to be phosphate ions $\left(\mathrm{PO}_{4}^{3-}\right)$. Sometimes it could be nitrate ions $\left(\mathrm{NO}_{3}^{-}\right)$as well. Because of these two ions becomes the limiting factor, the growth of algae in water bodies is controlled naturally. But by various human activities such as agriculture, disposal of industrial waste and addition of domestic detergents phosphate ions enter the water bodies. This eliminates the limiting conditions of the nutrient concerned ensuring rapid algae growth. This is eutrophication. If the algae growth has to be stopped, the phosphate level of the relevant water body should be maintained below 0.05 ppm . But in many urban wastes this phosphate level is high as 25 ppm .

Figure 1.39 Death of fish due to eutrophication

## Occurrence of heavy metal ions in water

Absence of a strict definition for a heavy metal not with standing, the following denotations are in use.

1. In metallurgy a heavy metal is described as a metal whose density is greater than $5 \mathrm{~g} \mathrm{~cm}^{-3}$ or a metal whose relative density stands above 5 .
2. In physics heavy metal defined as metal with the atomic number greater than 20.
3. In chemistry they are metals producing cations which give insoluble precipitates with sulphide ions $\left(\mathrm{S}^{2-}\right)$ and hydroxide ions $\left(\mathrm{OH}^{-}\right)$.

In some occasions these heavy metal ions are micronutrients (e.g. $\mathrm{Zn}^{2+}, \mathrm{Fe}^{2+}$ ). In many instances they are harmful and toxic (e.g. $\mathrm{Hg}^{2+}, \mathrm{Cd}^{2+}, \mathrm{Pb}^{2+}$ ). Some are indispensable element at low concentrations but are harmful at high concentrations (e.g. $\mathrm{Cu}^{2+}$ ). Some heavy metal ions do not contribute to any biological process. Heavy metals occur as sediments, deposits in soil, water and on the bottom of water bodies.

Heavy metals occurring as rocks, minerals and their debris in the Earth's crust enter the soil and water after the weathering of rocks. In natural water, heavy metals occur as hydrated ions and complex compounds. Table 1.13 lists the sources of few toxic heavy metals in water and their effects.

Table 1.13 Sources of a few toxic heavy metals in water and their effects

| Heavy metal | Source to water | Effect |
| :--- | :--- | :--- |
| As <br> $\left(\right.$ as $\left.\mathrm{As}_{2} \mathrm{O}_{3}\right)$ | Industrial waste water, waste of <br> phosphate fertilizers, ground water, <br> fungicides, ectronic items | Carcinogenic, arsenicosis |
| Cadmium <br> $\left(\mathrm{Cd}^{2+}\right)$ | Industrial emissions, mining waste, <br> metal refining, rechargable batteries | Enzyme deactivation, high <br> blood pressure, kidney damage |
| $\mathrm{Lead}_{\left(\mathrm{Pb}^{2+}\right)}$ | Industrial emissions, mining waste, <br> leaded gasoline, leaded paints, metal <br> pipe welding materials | Kidney and reproductive <br> disfunction, mental retardation <br> of children, anaemia, <br> inhibition of haemoglobin |
| Mercury  <br> $\left(\mathrm{Hg}, \mathrm{Hg}^{2+}\right)$ Industrial waste, traces in many <br> minerals, coal burning, equipment  <br> containing mercury (CFL bulbs, Brain damage, insomnia, <br> thermometers, vacuum apparatus)  | disease damage, minamata |  |

Figure 1.40 Effects of toxic heavy metals

## Dissoloved organic compounds

Dissolved organic compounds are compounds which are non - toxic but contribute to biochemical oxygen demand (BOD) or chemical oxygen demand (COD). Sugars, carbohydrates, lipids, fatty acids, amino acids, proteins, soluble hydrocarbons, primary and secondary metabolic products of plants and metabolic wastes products belong to this category. When these substances occur in water they are decomposed by bacteria. This increases the oxygen demand of water and decreases the dissolved oxygen level (DO). This impedes the biological processes in water.

## Toxic or hazardous organic compounds

Presence of these compound in water even in trace amount makes water unsuitable for use. Mostly persistent organic compounds belong to this class. Some pesticides, industrial chemicals, halogenated organic compounds, dioxin, furan, polychlorinated biphenyls (PCB), polyaromatic hydrocarbons (PAH) and disinfected by-products are examples for persistent organic compounds.

Given below are some organic compounds which are highly toxic or hazardous if present even in trace amounts in water.

Benzo(a)pyrene(PAH)

2, $2^{\prime}, 4,5,5$ ' - pentachlorobiphenyl (PCB)

Furan

Aldrin

Tetra-n-butyltin

Carbofuran

Water disinfection by-product are the chlorine containing compounds formed by the reaction between hypochlorite ions $\left(\mathrm{OCl}^{-}\right)$and some organic compounds dissolved in water. Hypochlorite ions are produced by chlorine $\left(\mathrm{Cl}_{2}\right)$ or hypochlorite salts (e.g. NaOCl , $\left.\mathrm{Ca}(\mathrm{OCl})_{2}\right)$ added for disinfecting water. These compounds are poisonous. Some water disinfection by-products are given below.

## Plastic additives

At present, virtually there is no consumer product devoid of plastic. Even if it is a food item, many plastic materials are connected with it. Few polymers are used to make all these consumer goods made of plastic. But do you know that many other additives are added when making plastic goods from these polymers? These additives are used to facilitate production, minimize cost, import various mechanical and workable properties and to get consumer attraction. These additives are ordinary chemical substances. During incorrect usage and when disposed to soil or water after use, there is a possibility of releasing these chemicals slowly from the plastic item. Some of these additives are hazardous. There are additives which cause cancer, affect the endocrine system and damage kidneys and various glands in the body. Escape of hazardous catalysts and monomers used in the synthesis of plastics from the finished product is also possible as traces. During the manufacture of plastic various additives are added to facilitate manipulation and mechanization. These also enter our bodies. Hazards additives also enter our bodies due to misuse of plastic items. A common example is the use of empty plastic water bottles to store liquids like coconut oil. Some additives in plastic bottels are insoluble in water but enter into non-polar liquids like coconut oil and enters our body.

Uses of some chemical substances commonly used as plastic additives and their effects are given in Table 1.14.

Table 1.14 Uses of some chemical substances commonly used as plastic additives and their effects

| Additive | Uses | Effects |
| :---: | :---: | :---: |
| Pthalates | Make plastics less rigid | Decrease the hormone secretion of endocrine system Carcinogen |
| Dioctyl phthalate | More flexible |  |
| Dimethyl phthalate |  |  |
| Di (2-ethylhexyl) phthalate |  |  |
| Leaded pigments <br> $\mathrm{PbCrO}_{4}$ (yellow) <br> $\mathrm{Pb}_{3} \mathrm{O}_{4}$ (red) <br> $\mathrm{PbCO}_{3}$ (white) | To get vivid colours to plastic | Central nervous system damage, slow mental growth in children, kidney damage, delayed growth, likely carcinogen, decrease the hormone secretion of endocrine system |
| Brominated flame retardants | Used as a flame retardant in plastic covers, electrical cables, carpets and in plastic layers | Accumilate in the lipophilic and bio membranes and affect the nervous system. <br> Decrease the endocrine hormone secretion of endocrine system |
| Decabromodiphenyl ether |  |  |
| Tetrabromobisphenol A |  |  |

Bisphenol A

Used as a monomer in polycarbonate plastics item (school water bottles, baby feeding bottles)
Used as an antioxdiant in the prduction of PVC.
Polymers of bisphenol
A is used as a protective coating for corrosion on the inner walls of metallic tin vessels.

Decrease the endocrine hormone secretion of endocrine system
Mimics the action of estrogen hormone and disturbs its action

Organ development issues in small children

| Additive | Uses | Effects |
| :---: | :---: | :---: |
| Monomers and catalytic residues in plastic products | Used to make polymers and accelerate polymer resin synthesis | Highly toxic, carcinogenic and mutagenic (monomer residues) <br> Neurological damage and |
| Styrene, vinyl chloride, Bisphenol A as monomers |  | Neurological damage and carcinogenic (catalytic residues) |
| $\mathrm{Cr}, \mathrm{Pb}, \mathrm{Cd}$ compounds as catalytic trace residues |  |  |
| Organotin compounds | Used as stabilizer in PVC and as a catalyst in Polyurethane production | Disturb the action of endocrine hormones in organisms Carcinogenic and mutagenic |
| Dibutyl tin and tributyl tin compounds |  |  |
| Polyaromatic hydrocarbons | Fillers in plastics, processing oil in plastic manufacture | Some compounds are strongly carcinogenic |
| Pyrene, benzopyrene |  |  |
